Hi Stefano,

You offer:
>I would love our chats were genuine ,technical, on the antenna....

It is your choice in what to respond to:
>Again I can explain all, I can explain why.
However, you chose not to go down the technical road, but rather you took the self-promotion road. Look at how many times you use the personal pronoun "I" above. [I lost track after 40, but it will supply an amusing follow-on.]

Instead we are offered the pathetic bumpkin:
> I am the accused....
such a poverty of technical discussion that so often attends these matters.

Thanks very much to all those who responded, although a fair bit of confusion remains in my mind, at least. Richard Harrison's explanation, below, seems to be a good summary of the equivalent circuit argument put by Balanis and many others which, it seems to me, limits the receive power efficiency to 50% of the power in the field since 50% must always be scattered (the term reradiated is also used, interchangably).

But ... There is a large literature on microwave transmission of power which claims measured overall efficiencies exceeding 50%.

Also, and closer to my own interest, there are a few publications about collecting solar energy with antenna structures instead of solar cells and they state that very high efficiencies are feasible. For example, John D. Kraus ("Antennas", 2nd edition, McGraw-Hill, 1988) proposes two orthogonal arrays of tiny dipoles and says "... 100 percent aperture efficiency is possible, in principle". In other words, all the power in the incident light wave over the physical area of the antenna can be delivered to the load, in principle.

Balanis agrees that 100% aperture efficiency is possible (ie. an amount of power equal to all the incident wave power enetering the physical aperture (of an aperture antenna) can be delivered to the load), but still says that an additional equal amount of power must be scattered (reradiated) when the load is conjugately matched to the antenna. Wher does this power come from? I assume it must come from the field beyond the aperture, so the antenna would be collecting energy from twice the area of its physical aperture. This may be OK but it does become interesting if the incident field is strongly concentrated within the physical aperture. I guess in that case the aperture efficiency must decrease to still allow an amount equal to the load power to be reradiated.

Another idea: Is there a trick embedded in all this, associated with the relative phases of the reradiated and incident waves and possible cancellation?

Thanks again,
Richard Corkish

Thread:

Ahhh.... come on guys. Dissipationless Resistance, higher than 50% efficiency in a conjugate match!!! What a bunch of balderdash!!!

Ya'll know that the only way you can get higher than 50% efficiency in the operation of any transmitter, amplifier, generator, or source it to:

OPERATE WITHOUT A CONJUGATE MATCH Heh, heh... [OR EVEN AN IMAGE MATCH (Lately called a Zo match!)].

By DEFINITION, if there is a conjugate match the efficiency of the source is EXACTLY 50%. Nothing more, nothing less!

That situation is simply what a conjugate match is, namely: a conjugate match practically defines the 50% efficiency design point for any source. Internal resistance of the generator equals the external resistance of the load. Half the total power is wasted in the generator and half goes into the load. The conjugate match, pretty simple.

Of course, any given source can operate at efficiencies much higher than 50% if it is not "matched".

So why operate at a match?

The electric power company doesn't operate it's generators at a conjugate match, your car battery doesn't do so, and neither does you flashlight. And any one able to discern and understand a schematic will see that literally no practical ham HF transmitter operates at a conjugate match either.

The problem that those who are confused by this fact have, is simply a problem they have with the semantics of issues completely unconnected with efficiency considerations, those of "wave mechanics" and "reflections". KISS... Keep it simple stupid. A conjugate match defines 50% efficiency, period!

Apart from some kinds of laboratory generators and test equipment, which are generally low power devices where inefficiency doesn't matter, and where a precise termination impedance is often demanded for metrlogical reasons other than efficiency, there is no good practical reason to operate most other sources at a "match". It's simply too inefficient to do so! So as the doctor said to the patient who was hitting his thumb with the hammer, "don't do that"!

Of course, as Roy points out, many common mortals have observed that sources can be, and usually are, much more than 50% efficient. I myself have designed many such sources, and shipped them to customers in the millions to

boot.

Now consider...

No "source designer" in "her" right mind would ever seek a conjugate match, or even an image match for that matter, when striving for high efficiency. The source designer will try her best to design every Ohm of resistance out of her source. What? You want resistance in a source? Silly!

The fact is that any source that is, operating into a load, and found to be exhibiting more than 50% efficiency is definitely not conjugate matched!

Now that being said... note that "load designers" might have different objectives and challenges than "source designers".

This is because a load designer' job is to try to extract the maximum possible power from an already prescribed and invariant source. Poor souls they are faced with the basic situation that, given a generator, there is nothing that they can ever do with their loads to simultaneously extract the maximum possible power and also cause the generator efficiency to exceed 50%! Of course, if they were not careful, they might cause the generator to melt down! I remember once a long time ago in "machines lab" when I... well you don't really wanna hear that story!

The load designer simply cannot change the source impedance, "he" just has to deal with it. "He" can only change the load impedance. The load designer can do no better than a conjugate match if "he" is trying to get a prescribed source to operate at maximum efficiency. The source designer however has no such restriction and can do whatever "she" wants to increase efficiency of "her" source.

The source designer tries to deliver the prescribed power to the load at the maximum possible efficiency, using three important principals: (1) eliminate resistance, (2) eliminate resistance, (3) eliminate resistance... conjugate match be damned.

Period, end of story!

(I'm sorry but I just can't bring myself to use that NBS/NIST invented phrase "Zo match", when for many decades we already had the fine name "image match" for the same damned thing!

For a conjugate match the load is the complex conjugate of the source impecance, e.g. if the source impedance is Zin=Rin+jXin, then the load impedance is Zo=Rin-jXin. For an image match the load impedance equals the source impecance, e.g. it is Zo=Rin+jXin.

Other than supporting the design theory of "image matched filter design" I have found the concept of the image match to be of minor importance. Anyone remember m-derived sections, constant-k sections, etc...?

Best,

--Peter K1PO

Honestly, I am looking forward to seeing his results - at least Ted Hart
hired an independent consultant engineer to do the tests properly... I only
hope I don't have to wait too long.
Till then, I simply will not believe any unsubstantiated claim... sorry !

Hello Stefano,
I asked for some good theory explanation many times, but yet I didn't get
any real equation to deal with (and yet Maxwell equations are valid...).
I5LHY also build an EH antenna which I've seen working and it never
seemed to be better than -20 dB over a simple dipole.
I only whish to see some real explanation, in terms of equations that
are still valid.

Which magazine? I don't think any ham magazine in Italy has an enough valid
technical level. IEEE magazines are the right place to publish new discovers.

The problem with antenna receiving antenna efficiencies of more than 50% is reciprocity. An antenna has the same characteristics receiving as it has transmitting. There is no one-way path. It`s difficult to sneak energy through a slit and trap it inside a container.

You may convert energy from microwave to heat, then trap the heat within a thermos bottle (Dewar flask?), or something of the sort. Light to electricity?

A parabola concentrates parallel rays through a focal point, coming or going.

Best regards, Richard Harrison, KB5WZI

Peter, K1PO wrote:
A conjugate match defines 50% efficiency period!"

Wrong! in general. Right, in the case of Peter`s dry cell. The dry cell has only the kind of resistance a resistor uses. It is the kind that dissipates energy.

A transmission line has a surge impedance (it`s a pure resistance in a perfect transmission line) which limits current to a specific value for a specific value of applied voltage. It`s the 50, 75, or so ohms value of coax, for example.

Apply some voltage to one end of a coax and terminate the far end in a matching resistor. There is no reflection when energy from our source arrives at our resistor. Energy is 100% absorbed by the resistor. 0% is eaten by our perfect, for practical purposes, coax. Why?
"Dissipationless resistance" in the coax.

The off and on switching in a Class C amplifier is another type of "dissipationless resistance".

Best regards, Richard Harrison, KB5WZI

Collimate antenna radiation well enough and all the energy exchanged between antennas is trapped. No loss in free space means efficiencies exceeding 50%. This would be like a lossless transmission line with reflections.

Thanks Bill;

I, too, used google a while back(nothing then) , and tried again at your suggestion.

It's great that there now is evidence that others have heard (and referenced) the second volume; so let me re-word my request:

Anyone know how I can obtain a copy to borrow or buy?

I do not have access to the stacks at the University of Western Ontario for example.

E-mail response should be fine.

Even with a Thevenin or Norton source, it's possible to get any efficiency you want (as long as it's less than 100%). For example, let's say you have a 100 volt voltage source in series with a 10 ohm source resistance. If you connect this to a 10 ohm load, 250 watts is dissipated in each resistor, for an efficiency of 50%. But if you use a load resistance of 90 ohms instead, you'll have 10 watts in the source resistance and 90 in the load resistance, for an efficiency of 90%. The efficiency keeps improving as you increase the load resistance (or decrease the source resistance). As someone mentioned earlier, power companies depend on this in order to supply power at high efficiency.

How about receiving antennas? The same principle holds. Here's what Kraus says, in _Antennas_, Second Edition, p. 34, or in the First Edition, p. 46:

"For conditions of maximum power transfer and zero antenna losses, the scattering ratio is unity. If the terminal resistance is increased, both the scattering aperture and the effective aperture decrease, but the scattering aperture decreases more rapidly so that the scattering ratio becomes smaller. By increasing the terminal resistance, the ratio of the scattered power to power in the load can be made as small as we please, although by so doing the power in the load is also reduced."

The scattering ratio os the ratio of scattering aperture to the effective aperture, or the ratio of power scattered from an incident wave to the power delivered to a load at the antenna terminals.

I highly recommend a careful reading of Chapter 3 of the First Edition or Chapter 2 of the Second Edition of _Antennas_ for anyone interested in receiving antenna concepts.

I repeat my offer... send me one and I'll measure it here and compare to a variety of vertical and horizontal antennas and report to the group, then if you like my results you can publish them. I don't want to spend the time to build one because there would always be the question (like the cfa example you cite) about how I built it and did I tune it properly. You build it, tune it, test it there, and then send it to me and I'll see what kind of results I get.

==========
There are no tricks. The field in the neighbourhood of a receiving antenna is distorted. It is the resultant (the sum) of the original and re-radiated fields.

In some directions the original field will be reinforced, in other directions there will be partial cancellation.

Distortion depends on orientation of the antenna relative to the original field.

Greatest field distortion occurs when the receiver is short-circuited and ALL intercepted energy is re-radiated.

I know exactly how it works.

You have been talking about this antenna for some time and claim that its a new discovery and no one understands how it works. To make these claims you must have some measured data.

So, to support your claims please provide the following information. Maybe then we can evaluate your claims and decide for ourselves.

1) Please provide a drawing of the antenna with dimensions.

2) Please provide a description of the measurement setup.

3) How high was the antenna above ground?

4) What were the ground conditions?

5) What was the test frequency?

6) What impedance did you measure without the "matching network"?

6) What impedance did you measure with the "matching network"?

7) Provide a description of the matching network and component values?

8) How did you account for ground impedance affects and common mode currents?

This should get us off to a good start for discussion.

I used the same excuses and was dead wrong while doing it.
All of the money that I paid in rent was lost, versus
gaining equity in my own property.

In today's world, the landlord expects you to pay ALL of his
expenses (including a mortgage) AND pay him a profit. It is
business. That is how it works.

I don't know where you live, Jason, and maybe that is the
problem. But here in the US, if you can rent, you can own.
You may have to be creative in your financing (Carlton
Sheets real estate course is fantastic), but it CAN be done
if one works at it. Selling property is not difficult if you
buy carefully to begin with.

Anyway, good luck in your apartment ham shack (shudder! -
BTDT).

for what is worth, I'm sure there are many hams even closer to Stefano who
would like to test a "well made EH", even I could do it,
I'm a telecommunication engineer and of course I can compare the
antenna with the presence of a lot of other hams and technical qualified
peoples.

Jason:
Here are a couple of points I don't think anyone else mentioned, in addition to the height and clear location.

1. Check each possible location with a portable SW receiver, preferably day on 20 M and at night on 40 or 75 M for noise and signals. Pay attention to computer and power line noises, as these won't go away. An AM/FM receiver isn't going to tell you much. The transmit/receive balance is wrong. Hams use low power and receive weak signals, while commercial broadcasting uses 100 or more times as much power and insensitive receivers.

2. Drive around the immediate area with a mobile receiver on 75 or 40 and listen for loud power line noises. Again, the likelihood of these getting fixed are slim these days, and with a good antenna at your apartment, you will hear these from a distance. Preferably, the location would be in an area with underground power feeds.

Roy, W7EL wrote:
"By increasing the terminal resistance, the ratio of the scattered power to power in the load can be made as small as we please, although the power in the load is reduced."

If the load matches the antenna, no power is reflected by the load to be re-radiated, but the antenna is excited by the wave sweeping by and divides its power equally between equal parallel loads, the receiver`s input resistance and the antenna`s radiation resistance.

Radiation resistance is a function of antenna length.

If an antenna doesn`t receive much energy, it can`t re-radiate much.

An account of energy acceptance is given by John E. Cunningham in "The Complete Broadcast Handbook": "As construction progressed (on a nearby microwave tower), the current in one tower (of a 4-tower directional array) continued to drop as each new section was added to the microwave tower. The current continued to drop until it nearly reached zero. But, as more sections were added to the microwave tower, the current began to rise. When the microwave tower reached its full height, all the tower currents of the broadcast antenna, as well as its pattern were normal."

A grounded tower near the broadcast array accepts the most energy at 1/4-wave resonamnce as illustrated by Cunningham`s story.

Were the microwave tower erected on a base insulator and not cionnected with the earth, it would have become resonant when it reached 1/2-wavelength.

Resonnant structures sited near a broadcast station must be detuned so as to not interfere with the broadcast signal.

Let`s say we want maximum excitation of our receiving antenna. We make it resonant. The only way to get maximum power from the antenna is in a matched load.

A higher load resistance may produce higher voltage but the current we can draw is reduced so that the product of volts times amps is smaller than we can get from a matched load.

If the load resistance is made smaller than a match to the antenna, the current may increase but not enough to offset lower voltage across the load. The load loses power and reflected power from the mismatched load increases re-radiation.

Re-radiated power can be reduced by reduced excitation.

Reradiated power can be increased by greater mismatch of the antenna`s load

An open-circuit 1/2-wave and a short-circuit (grounded) 1/4-wave may be highly excited but are completely mismatched. They re-radiate all of the energy they receive.

Best regards, Richard Harrison, KB5WZI

Richard

You can get an angle on this problem by first considering a plane wave
normally incident on a conducting plate. The total power in the field
is unchanged by introducing the plate, but there are two main region of
scattered field, one back towards the source (the reflected field) and
the other continuing in the original direction (the forward-scattered
field). Each of these scattered fields has a main lobe and a set of
sidelobes of the usual sin(x)/x type (at any point the scattered field
is defined as the actual field minus the original field that would have
existed without the plate).

Both the reflected field and the forward scattered field have the same
total power, equal to the area of the plate times the power density of
the incident plane wave. The total field power is the same with or
without the plate.

NOW put a dipole array on the forward side of the plate, all dipoles
feeding matched loads. The loads then (ignoring practical effects like
ohmoc losses) absorb a power equal to the area of the plate times the
power density. Furthermore the reflected field no longer exists, so
that the power that was in the reflected field is now absorbed in the
load.

BUT the forward scattered field is still there unchanged. However, the
total field power is reduced by the amount of power absorbed in the
loads. This is possible because there are regions behind the plate
where the total field is reduced, e.g. immediately behind the plate the
scattered field is in opposite phase to the original field, so that
there is no field at all. Therefore the original field added to the
forward-scattered field has a total power equal to the original power

minus the power absorbed in the loads.

The situation is thus:

1. power in loads: area times power density,

2. forward scattered field power: area times power density,

3. reduction in total field power: area times power density.

This is how Balanis conjures up a scattered field without violating energy conservation.

Alan

> cancellation?

Lets try a sanity check. An EM wave is an EM wave is
an EM wave, so lets consider a hollow sphere with a
small hole in it with the inside coated with lamp
black. Shine a narrow beam laser into the hole and
pretty near 100% will be absorbed.

So, it is possible. What is special about this
case? My guess is it is that the aperture is enough
larger than the beam. A similar situation could
apply to a microwave beam and a recttenna farm.

I believe Balanis refers to the case of an antenna
in a plane wave field where the extend of the field
is much wider than the antenna aperture.

I have to agree. I am in the same position as Jason now. Apartment complex with absolutely no chance of an outside anttenna. I know because I asked. I was forced to remove my satellite dish or face eviction. I can't put anything on the roof, because they recently re tarred the roof, so not everyone can afford that luxury. I am content with my mobile operation for now, but during a 48 hour contest it just doesn't cut it. With what I am paying for rent I can easily afford a comfortable home. But I haven't quite saved enough for the down payment. I have an area in mind (no power line noise) so it is only a matter of time before I will have enough to put down on a house.

Good luck Jason,

1526. Estimating ground plane efficiency

I'm trying to estimate as closely as possible the efficiency (pwr radiated over pwr delivered by feedline)
of my 14 MHz ground plane. This antenna has 9 "drooping" radials (c. 40 deg. below the horizontal) to raise its
impedance to 50 ohms, and the SWR is 1.0:1 The base of the vertical radiator is one quarter wave above ground
(which is dry desert stuff). I'm just guessing perhaps 90 percent, but can anyone with experience or references
in this area help out?

You might want to check with the FCC on the satellite dish. I was under the impression that, to help the satellite companies compete with cable, the FCC has mandated anyone can put up a satellite dish, regardless of where they live. The snazzy apartment complex I was last in, in Houston, had user-installed dishes all over the place.

Is any part of that 377 ohm impedance actual resistance, so that there
is dissipation or conversion to heat at the interface between the
antenna and space?
As to what is re-radiated, is that at the same frequency as the
original wave, and what would prevent putting up another antenna to
capture what was re-radiated and combining it with the original to get
more than 50%?

Jim, SWR on the feedline has nothing to do with radiating efficiency of the antenna.

Assuming no loading coils and the aluminium antenna conductors have diameters large enough to be self-supporting, loss in the antenna itself is absolutely negligible. (thin wire antenna loss is higher, crudely 3 %)

Above 'dry desert stuff', at that antenna height above ground, considering the large number of radials, and assuming there are no other structures in the vicinity, power loss in the environment is negligible. But to give it a number, let's say 2 percent.

So the radiating efficiency of the antenna + ground is about 98 percent.

Considering the system as a whole, depending on type and length of feedline, most of the loss almost certainly occurs in the feedline. A line attenuation of 1 dB corresponds to a 20 % power loss.

Hi Tom,

You are doing your best when it comes to checking the radiative path of interference, but there is also the conductive path.

That is, if your TV and transmitter share the same 120VAC circuit (they go to the same breaker), there is every chance that is the means of coupling.

Move the TV's or the transmitter's power connection to a separate circuit (breaker). If this clears up the problem, you might be able to reconnect to the original circuit (if a necessity of the apartment layout or other consideration) and use snap on suppressors around the power lead(s). Snubbing the transmitter's lead is preferred (stop the interference at the source).

John O`Flaherty wrote:
"Is any part of that 377 ohm impedance actual resistance, so that there is dissipation or conversion to heat at the interface between the antenna and space?"

No.

The loss in energy as distance from the transmitter grows, all comes from a constant power spread over a larger surface area as the radiation bubble grows, in free space.

Now, as a radio wave travels along the surface of the earth, it is sapped by the imperfect conductivity of the earth`s surface. Earth loss adds to the attenuation caused by the expanding energy bubble. But, the earth has already boosted power in the bubble over what would have occurred in free space by reflection of the energy which is blocked by the earths surface. Access to a hemisphere down there is denied. So this reflected energy adds to direct radiation from the transmitter.

377 ohms in free space is like 50 ohms in lossless coax. It is a lossless voltage to current ratio that can be depended on.

John also wrote:
"As to what is re-radiated, is that at the same frequency as the original wave, and what would prevent putting up another antenna to capture what was re-radiated and combining it with the original to get more than 50%?"

Good thoughts!

Unless there is loss resistance in a receiving antenna, re-radiation is all at the original frequency. Loss in a resistor converts r-f to heat which may be radiated along with remaining r-f. Heat is energy of a different frequency from the r-f.

Parasitic arrays have elements not directly connected with the feedline to a transmitter or a receiver. These disconnected elements re-radiate their intercepted energy to combine with that of the directly connected elements. This configuration is made with the intent of enhancing performance.There are other entries in this thead about multi-elemnt arrays. They concentrate enrgy but don`t create energy.

Doc, W5LZ wrote:
"---a "shorting" stick is the exact opposite of a "hot stick".

That`s right, but I said I used it backwards!

A hot stick is what the power company uses to operate switches and breakers on those utility poles where there`s high voltage. It is also what I used to open and close ammeter shorting switches where there was very high r-f voltage.

There are interlock circuits to keep transmitter operators from encountering live circuits. When trouble-shooting, you bypass those interlocks, enter the transmitter, and poke and probe with the best you have, and that is usually that shorting stick used in reverse. That grounded hook in your hand (you keep the other hand in your pocket) makes the insulated grounding stick very safe to contact high-voltage parts. Even if there is current leakage it will go to ground through the hook ground cable and not through the operator.

Best regards, Richard Harrison, KB5WZI

Hi Jason,

This is simply a prejudice, but I would suspect that those models
under $200 are suitable in Europe only where there is a high density
of SW traffic (large signal, low sensitivity receiver). Try finding a
Radio Shack DX-440, or its Sangean label, or similarly spec'd
receiver. Do not count on the whip, but rather use the external
antenna connection of about 20' of wire (tossed across the carpet is
enough care for a casual inspection of HF frequencies; especially for
the BBC, VOA or DW). I would also suggest checking the standard
frequencies for WWV(H) as they are clear channel and spaced throughout
HF to give a simple propagation snapshot.

The DX440 (many years ago) cost $200 and is what I would consider the
low end. You might find one at half that price (as well as its
similarly performing kin) at a swap meet, but that may take some
hunting.

I disagree with this interpretation. The way I look at it, and I will
be happy to hear your opinion on this, is that free space is a
transmission line of wave impedance Zo = 377 ohms to which the
transmit antenna acts as a matching transformer between the
transmission line and the generator. The receiver antenna does the
same for the load.

Of course, this "transmission line" is directional in the sense that
in each specific direction there is a specific TEM mode propagating
and there is a secondary and a line associated with it. So actually we
have not one but an infinity of transmission lines all in parallel and
connected to transformers whose turn ratios are proportional to the
directivity. The higher the antenna gain, the narrower the beam is,
the more this picture represents a single "dominant" transmission
line.

When you have matched the antenna properly, the return loss from the
generator or load end is very high. From this point of view a matched
antenna does not scatter the received wave at all, on the contrary, it
capture everything incident to its effective surface area and delivers
that to the load.

If you think of it this way then you see that half the power has
already been eaten in the source impedance of the transmit antenna's

generator. Free space being the medium of transfer only and not being an internal impedance of any generator, will not absorb any part of the power incident to the receive antenna if that is matched. But bear in mind that matching is directional, that is if it radiates with its source in a perfect match in one direction d1 and not at all in another, say d2, then it will not scatter an incident wave from direction d1 but will scatter one from d2.

You can see this also by the following argument based on a "gedanken" experiment. Take a pair of long and gently sloping waveguide horns with matched probes. Wnen they touch there is a perfect match. Now separate them beyond the Rayleigh distance. There will be a frequency band where despite the separation they will transmit and receive if they were still touching.

Thanks for the suggestions/help.

I'm not sure I'm following you. I seem to have a different interpretation of what this gain limitation (i.e. Industry Canada's RSS210 Section 6.1.4 Part (3)) means. I have been viewing the whole thing from the perspective of directivity. As I understand it, if you shape, etc an antenna so that it's emissions cover only half the area covered by an omni-directional radiator, then you have created an antenna with a gain of 3bB. The further you reduce the area into which you confine you're emissions, the higher the gain of your antenna. The efficiency of the antenna (at converting transmitter power to RF energy) can go right down the tubes, the antenna itself has an "inherent" gain value determined solely by the way it focuses whatever power it does manage to radiate.

If I understand what you're saying, (and I probably don't), I need to be adjusting efficiency, etc so that at some distance away, in the most favored direction I guess, the signal strength does not exceed what it would if I were using a half wave dipole with the same transmitter power. Problem is RSS-210 specifies lots of specs regarding what the signal levels shall be, at what distance, within what band width, etc. At the moment I think the what they mean is the "inherent" gain figure associated with the type of antenna being used. I'm still wondering if the gain of a small loop antenna isn't greater than that of a half wave dipole because it confines more of the energy it emits into a smaller area around it. There is no doubt however that it is much less efficient at producing RF energy from a given amount of transmitter power.

I guess what I really want to know is:

If I walk into the Industry Canada lab (or FCC lab since I'm pretty sure the regulations are identical) and say I want the OK to produce and distribute this thing as license free RF device, would they say :

a) No. It has a small-loop (.08 wavelength) antenna and regulations say you must use an antenna with a gain less than a half wave dipole.

b) No. By surrounding the antenna with all that shielding you created something other than a small-loop radiator. That thing has a directivity (i.e. a gain) much greater than a dipole and it's illegal.

or
c) We'll need to take field strength and spectrum analyzer measurements first.

Again, suggestions appreciated,

Mike Whitfield

It's going to be fairly high. With 9 radials at a 1/4 wl up, you are
about equal to having a ground mount with 120 radials. I had a 40m gp
at a 1/4 wl up with 4 radials. On that one , I came to the conclusion
it was about equal to a ground mount with 60 radials. So you should be
doing very well. As far as the exact number , it's kind of hard to
guess on this end. But it should be in the 90's % range. MK

My receive antenna, while it is the act of
receiving, is also a transmitting antenna.

My received signal sets up (excites) a wave motion
in the wire. This wave motion is free to radiate
exactly the same as if it were created by my
transmitter.

In equilibrium, the previous statement is true.
The received signal power that is delivered to my
receiver input terminals is equal to the
received signal power that is re-radiated.

An equivalent statement is that the receive
antenna is a kind of "reflector" for the incoming
wave. If a receive dipole is shorted at the center
the reflection is 100 percent. If the right
resistor value is there the reflection is 50 percent.

Hi Guys, 2 things to reduce the guessing:

1. Measure the feedline loss by putting a GOOD short circuit on the
feedline
where it connects to the antenna and measure the return loss at the
other end
in the shack. It should be about a dB or two as Reg said but you
didn't specify any length or type; it could be lossy.

2. Determine the validity of the low loss assumption for the radials
by removing them one by one and measuring the impedance of the
antenna. If you ideed have an effective zero loss ground plane (which
I doubt) pruning one or two radials shouldn't change the antenna
resistance.

This is really a lot of trouble to go to to find out something that
you
probably don't want to know in the first place. If it works, don't
fix
it. So, _does_ it work? Or is that why you're asking!! Keep in
touch,

Exactly. Bill already said his system was in equilibrium. It is matched.

There is no infinity of transamission lines or previously attenuated signal out there as speculated by another contributor. What you see is what you get.

The 377 (120*pi) ohm impedance of free space is a pure resistance. It is not a resistor. It's the ratio of the E field (volts/meter) to the H field (amps/meter) of a plane wave traveling in it, so it has the dimension of ohms. Similarly, the characteristic impedance of a lossless transmission line is a pure resistance, but isn't a resistor. Another example of a resistance that's not a resistor is the transimpedance of an amplifier, the output voltage divided by the input current.

No part of a traveling wave is converted to heat by moving through free space or a lossless transmission line, because it isn't current passing though a resistance or resistor.

HI.

Although I have done HF for quite a while this 2m stuff is new to me.

I recently purchased a ICOM T2H handheld and I would like to hook up a 2m antenna at home.

My questions are these.

1. Can I use an antenna up in the attic for VHF?

2. What kind of lead should I use to connect the antenna to the radio. With outputing only 6 watts, I can't afford to lose much.

I figure if I "get into this" 2m stuff more I can look at a more suitable base station but for now does this make sense?

Thanks for any help.

George

EZNEC will give you a very good estimate, and the free demo program would be adequate. You can get it at http://eznec.com.

For the efficiency of the antenna itself, compare the feedpoint resistance of the model antenna over ground to the feedpoint resistance of the antenna modeled in free space. If what you want to know is what fraction of the power makes it to distant points after being subject to ground reflection, look at the "Average Gain" value, which is the total power arriving at distant points divided by the power applied to the antenna. If you make changes in the antenna that affect efficiency (such as raising or lowering it, or changing the number of radials), these changes in efficiency will cause a corresponding change in the "Average Gain".

Another way to get the efficiency of the antenna itself would be to look at the "Average Gain" with the antenna high above the ground, where the efficiency should be near 100%, and compare this to the "Average Gain" at its actual height. The difference represents ground loss near the antenna.

Unless the roof is metal you can put the antenna in it if you want.
Sometimes there is lots of metal objucts in the attic and that might
need to be looked at but if no big objects there you should be allright.

If the run is not to long (under 50 feet) you might want to use the
rg-8X type cable. If longer then use the larger rg-8 type cable. You
probably want to use a few feet of smaller cabel from the HT to the
large coax to keep from breaking the connector on the HT.

For an antenna in the attic, you might just want to try a simple ground
plane. Strip off about 19 to 20 inches from the end of the coax so only
the center conductor is left, then where the braid is use 3 or 4 stiff
wires connected to the braid about 21 inches long and slope them down
about a 45 degree angle.

For working repeaters it does not usually take very much of a station.

Robert Egri wrote:
"---free space is a transmission line of wave impedance Zo = 377 ohms---"

Consider that a transmission line has an attenuation of a certain number of db per mile regardless of the distance from the sender.

Out of a sender`s near field, the attenuation due to radiated signal spread in free space grows by 6 db every time the distance from the sender doubles. At two miles the attenuation of a radiated signal has grown by 6 db from the attenuation of that signal at one mile`s distance. Fortunately, at 200 miles distance, the attenuation of a radiated signal has grown by only 6 db from the attenuation of that signal at 100 mile`s distance from the sender.

The farther we get from the sender in space, the more miles per db loss we get. Not so with a transmission line.

Best regards, Richard Harrison, KB5WZI

Thanks. Kraus and Balanis (and others) agree that "for conditions of maximum power transfer and zero antenna losses the scattering ratio is unity". In other words, as much power is scattered as is delivered to the load. However, it does not follow that only half the power entering the aperture of an aperture antenna can be delivered to the load. Balanis (2nd edition, p. 86) states that the aperture efficiency can be up to 100% but "even though the aperture efficiency is greater than 50%, for a lossless antenna under conjugate matching only half of the captured power is delivered to the load and the other half is scattered. Hence, the full captured power must be extracted from an area twice as large as the physical aperture. Hence, an aperture antenna must "shade" an area twice its own size. So if I want an array of collecting apertures (to collect solar energy, say) would they need to be spaced apart, covering only half the ground, to collect maximum energy (which is half the energy falling on the total ground area, since half of the collected energy from each aperture is reradiated).

Note that Samuel Silver (1949, p. 43) and Ramo, Whinnery and van Duzer (1994, p. 669) reject this idea of an equal amount of power being reradiated.

Roy's example well demonstrates the problem of using the Thevenin equivalent circuit here. The problem is that as we change the load or generator impedances, the power being supplied to the circuit varies. But that is not what we want to model when considering a receive antenna in a field with constant power flux. Varying the load away from the matched condition, as in Roy's example, can improve the fraction of the generator power delivered to the load but only at the expense of reducing the amount of power delivered to the load (since the power produced by the generator reduces as the total impedance increases and current decreases).

1556. MOBILE helical help...?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-25 01:18:56 UTC
From: Gary - KJ6Q <davison7@gte.net>
Message-ID: <2o248.869$0Q5.308653@paloalto-snr2.gtei.net>
Source record: 150293

OK, here's the deal...

I'm wanting to construct a mobile antenna for 7.2 mhz with an efficiency of 70% or better (relative to a reference dipole). I need a PHYSICAL overall length of about 11 feet - to be composed of a 5 foot lower section 3/8" fiber-glass shaft, a loading coil, and an upper section of 6 feet or so of the same material as the lower section, or part shaft, part whip... Measurements are SOMEWHAT flexible, but overall length is not, if I am to keep it outta the trees and overhead wires.

NOW, available ï¿½puter programs tell me I need an ELECTRICAL lower length of 6 feet, a 3 inch diameter coil of 12 ga. wire, and a top section with an ELECTRICAL length of 8 feet to reach my goal - and by the way, I am running a 6-700 watt PEP amp in my mobile as well...

SOooo, I am in serious need of a pointer, or info on helical winding as commonly used in antennas of this type, not necessarily as the loading coil itself, but as a tool to electrically alter the electrical length of other system components - is it practical, can I expect to wind enough wire or similar material on the upper and lower sections of my antenna to "fool" the system into thinking and functioning as tho' it is a physically longer system?

Is it practical or possible to merely employ a CB or ham band monoband whip, such as 17 meters in a system like mine to electrically simulate a longer length? It would be great if a standard existing monoband antenna could serve as both the top element of a 40 meter setup, and also be used on it's basic band as well! (Not in the same physical configuration, of course...)

Does helical winding, such as used on Hamstick and similar antennas provide actual INDUCTIVE loading, longer ELECTRICAL length, or BOTH? And at what point do I reach tradeoffs that start defeating my goals? Is there ANY reliable, accepted source of helical RF facts and guidelines I can access via the internet?

I'm really looking for actual, proven feedback or info here, not off-hand guesses or wild speculation - surely there is SOME source of program or test data to provide a basis for intelligent choice...

Any help?

If you are talking about a resonating system in thermal equilibrium
then yes this is how harmonic oscillators behave. But an incident
coherent radiation, say a plane wave, is not thermal radiation and
does not have to be in equilibrium with anything: the reradiation does
not have to be the same going in the opposite direction. As an
analogy, recall Huygens's principle, that is that every point of a
wavefront acts as a source of secondary wave but these sources
"radiate miraculously" in only the direction of the propagation.

Roy, I am not happy about including in an antenna radiating efficiency budget, loss/gain involved in upward reflections from the ground, in the near vicinity of an antenna.

That particular mode of loss/gain is OBVIOUSLY just as much a part of the radio path loss as is the loss in passage through the ionosphere plus distant losses involved in more distant reflections from the ground which occur in multi-hop ionospheric radio paths.

I know EZNEC is programmed to include the moderate loss/gain due to upward reflections from the local ground when predicting overall Tx to Rx field strength on very long paths. It is, of course, a valuable facility provide users are aware of the limitations.

But the facility should NOT be involved in the radiating efficiency of the antenna itself. It under-estimates antenna efficiency because it ignores the considerable very low angle ground wave radiation which propagates to distances far beyond the antenna near field. It is the vital principle on which LF and MF broadcasters depend.

Errors in predicting antenna efficiency may not be large because most power is radiated at higher angles. But when predicting ground wave propagation EZNEC invariably predicts zero-angle radiation, the groundwave, to be zero, which is obviously incorrect. A considerable error exists up to elevation angles of 5 or 10 degrees.

Provided users are aware that EZNEC predicts field strength only beyond the one-hop skip distance, usually long after the ground wave has fizzled out, all is well.

But I suggest most users would prefer an antenna modelling program which predicts the TRUE radiation pattern in the vertical plane, just outside the near field, and allow the user himself, if he so desires, to deal with path losses in the ground wave, in the ionosphere, in multiple-hop ground reflections and in the ground reflection loss/gains at the receiving antenna.

Ideally, the field strength at 1 km, in dB relative to a radiated power of 1 kW, at any elevation angle, is what is wanted to remove all confusion.

It makes me cringe to see EZNEC-produced radiation patterns of vertical antennas falling back to zero field strength at zero elevation angle. (Believe me I am not decrying EZNEC's usefulness. I have no wish to incite riots. ;o))

It may be that later versions of NEC programs allow correct interpretation of radiation patterns. In this day and age such programs must already

exist. I'm sure the Germans, Russians, Chinese, Indians, Japanese and others
have had them for years.

I don't consider myself a hardcare shortwave listener - in fact, I
have never owned a shortwave radio. My reasons for buying one are for
casual shortwave listening and for hunting noise sources. A digital
frequency display would be an added bonus, as it would allow me to
listen to myself (and thus correct any transmit audio problems I may
have). I don't want to pay a lot of money for a shortwave radio, as I
already have a transceiver for HF, and the Icom 706 MKIIG I intend to
replace it with also has shortwave listening capabilities.

I'll certainly consider a used Radio Shack shortwave receiver as well
as the MFJ receivers. Since the MFJ radios don't have the digital
display, I should probably lean towards the used Radio Shack models.

Get this: I send a package to Colorado via UPS. I label the package with the printed Label ups.com gives you when you have an account with them. I drop off the package at an "Authorized UPS Shipping Center" because it is insured for $3,400 and that is what UPS requires. I get a receipt from the shipping center stating that the item has been properly packed and labeled. OK so far... Four days later a guy in New Jersey at a communications business calls me. "We have your package and we don't know why it came here, but we opened it and read your letter inside. Looks like it is supposed to go to Colorado, what should we do with it?" I tell the guy thanks for calling me and I will call UPS and get back to him. I call 1-800-pickups. The first "support" person hangs up on me. The second says I "should take it up with the shipping center" (all they did was hold it for the truck pickup, the UPS driver in reality should have scanned it upon pickup). I ask to speak to a supervisor. The supervisor is cooperative and I tell her I want the thing overnighted from New Jersey to Colorado since it is "Guaranteed" to be there tomorrow by UPS. She says, "OK, I will call NJ UPS and set that up, they will call you in one hour or less." I thank her VERY much and ask for her name, title, and location. She complies. I am a happy camper. One hour passes, no call, two hours pass, no call. I call UPS back and ask to speak to this individual and... No such individual exists!! By this time it is late so I call and get another person in the morning who tells me to "take it up with the shipper..." I ask to speak to HER Supervisor. Her Supervisor says she will investigate and get back to me.... 7 hours go by. I call her and ask for a status report. Luckily, "she exists." Her answer? "Sir, since the package arrived in NJ and it was signed for; it is considered a completed delivery." I ask, incredulous... "What about my package?" "Sir," she says, "You need to contact the individual in NJ who has your package and ask him to forward it to Colorado for you. Since it was never scanned into our system there will be no charge." UPS at no time took responsibility for this transaction, despite my signed receipt. At no time did they offer a viable solution to a problem they created. At one time I received FALSE information from a UPS employee just to get me off the phone. Hence; I WILL NEVER DEAL WITH UPS AGAIN, and I would urge all persons to carefully consider all other alternatives before trusting anything of value to UPS. Only through the kindness and honesty of an individual in NJ was I able to locate and send my package to its proper destination. Rest assured, when it gets to Colorado, it will not have passed through UPS hands.

Richard Corkish wrote:
"Kraus and Balanis (and others) agree that "for conditions of maximum power transfer and zero antenna losses the scattering ratio is unity." In other words, as much power is scattered as is delivered to the load."

In yet other words, for maximum power transfer into a receiver under ideal conditions, as much power is re-radiated by an antenna as is absorbed in the receiver`s resistance.

Roy gave us an example of a 100-volt source in series with its internal resistance of 10 ohms. Maximum power transfer delivered 250 watts into a matching 10-ohm load. This gives an efficiency of 50%.

The same generator delivered 90 watts into a 90-ohm load for an efficiency of 90%.

No surprises. The 10-ohm internal resistance could have been antenna radiation resistance, and the 10-ohm and 90-ohm loads could have been receiver resistances.

The receiver designer usually wants all the signal he can get from an antenna, and he gets it from maximum power transfer. High efficiency does not give him the most signal.

Corkish may be interested in wireless power transmission. If so, antennas on the generator and receiver need to collimate the radiation so tightly that the receiving antenna captures all the energy in the column and none spills over the edge. A similar antenna on the sending end would capture all the re-radiated energy from the receiver. Thus, no energy escapes in space.

Corkish may be interested in capturing an r-f spectrum band of energy from the sun falling on a descrete area. In this case, the area neads to be shaded with a parabola large enough to confine the reception beamwidth to a disk exactly covering the sun`s disk. No larger and no smaller, to get the maximum energy from the sun at these frequencies on this area. 1/2 the received energy will be returned to the sun, but the best solution to more received solar power in this case is probably a second similar dish over a second plot of earth.

A solar-electric panel doesn`t necessarily reflect half its received light energy (insolation?) towards the sun or elsewhere because it converts the sun`s rays to electricity which isn`t reflected.

Your "Radar Range" converts microwaves to heat which isn`t instantly re-radiated. Change of the energy`s form is a way to trap energy for a while, but does not stop an excited antenna from re-radiating at least

1/2 of the energy it receives.

Best regards, Richard Harrison, KB5WZI

1562. Goofy Antenna Problem

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-25 03:33:03 UTC
From: John Reed <jreed@NOSPAM.thor.atl.ga.us>
Message-ID: <u51kfht28dm935@corp.supernews.com>
Source record: 150298

Here's a fun one:

My friend has a Ford Explorer. On the left rear, just near the "gas cap" he's got a ball mount. The ball mount is mounted thru the hull of the vehicle. He has 50 ohm coax coming off the ball mount to his radio. The cable is good. The connections are good - no shorts. There is good ground available.

Now here's the catch:

He's tried several antennas - a "whippet" 10/11m base loaded thing, a 10m "hamstick", a 10m quarterwave whip, and a 6m "hamstick'.

I used an MFJ meter and a different mount - a mag mount temporarily stuck to the middle of the hood and tuned all the antennas to minimum SWR.

When the whippet and the hamsticks are put on the ball mount, we can get no better than 3:1 SWR on the bands they are rated for. The 8 foot whip gets us down to around 1.6:1 on
10m.

Any reason why we're getting these goofy SWR readings? Again, if I take these antennas and put them on my vehicle, or on the magmount on his truck, they tune fine - but on the ball mount, the SWR goes to pot.

There was an on-glass antenna (2m/440) on the window right by the ball mount - but we've disconnected the antenna and the feedline, leaving just the on-glass thing.

So - why would an antenna that's tuned as good as it can get and performs well on other mounts display poor SWR when placed on the ballmount?

Anything we should be looking for? Could the on-glass thing be screwing up the antenna? We even took off all roof-mount antennas, too, just to make sure they weren't doing something odd to the equation.

Thanks in advance. Replies here to the newsgroup, or direct to me in email (remove the NOSPAM from my email address) are fine.

Next time the truck tips over (for whatever reason - some blame the tires), try to get it to come to rest on the right hand side (so that the left hand side of the truck, with the antenna ball mount, is facing skyward). Then clamber out, dust yourself off, and adjust the ball mount so that the antenna points upward - directly away from the ground plane, I mean, directly away from the truck's left hand side. Then retest your assorted whips. Good luck.

Gary,
You said, "Does helical winding, such as used on Hamstick
and similar antennas provide actual INDUCTIVE loading, longer
ELECTRICAL length, or BOTH?". They are basically the same thing,
so the answer is yes. I can understand wanting to build your
own antenna, but there are enough commercially made mobile
antennas around that would fill your requirements, that it's
sort of like re-inventing the wheel. Using 'standard' masts,
coils, and whips, you should be able to put together a 40 meter
mobile antenna very easily.
When you say you want 70% efficiency out of a mobile antenna,
I'm afraid you dreaming...

How far and how close is the antenna to the side of the Explorer. I am
not faniliar with that vehical and where the gas cap is located. If the
antenna is close to the metal then that could be the problem.

John,
Your readings aren't 'goofy', they are normal for antennas
mounted in different locations/environments. Use your MFJ
meter and tune the antenna ~on~ the ball mount.

Here's one
http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1326125547
They seem to top out at around $50-60 on ebay.
I've got SW radios scattered from one end of the house to the other and
this is a hard model to beat for the price. It lacks SSB and an alarm
clock. I bought mine because I was looking for a replacement for my
throwaway cheapo 19.99 chinese model analog 'yard' radio which crapped
out. A replacement for it (Coby) would have still cost $20 and is a
really crappy radio.
This DX-375 is the cat's meow in the price range. I have a 5kw AM-BC
station about 1/4mi away that drives many ss radios nuts...not this
one. And even tho its single conversion, you have to struggle to find
images on it. Great as a piece of test gear for calibrating the sig
gen, checking HF osc circuits, etc. too!
-Bill

Jason, I bought a used Grundig Yacht Boy 400 from a friend of mine.
It is superb for tracking down noise sources. It not only covers
commercial AM and FM but LW and most of HF including a BFO for
CW and SSB so it can even be an emergency backup ham receiver.

"William E. Sabin ---wrote---:
My receive antenna, while it is in the act of receiving, is also a transmitting antenna."

Robert Egri also wrote:
"Only if it is mismatched but it can be matched so it does not radiate anything."

Bill Sabin got it right. Every receiving antenna re-radiates at least 1/2 the energy it receives. The 50% minimum re-radiation occurs with a perfect match.

The reason is clear. The antenna doesn`t care where the energy exciting it came from. The antenna doesn`t know if it is supposed to collect energy or emit energy, so it does both.
When the receiver load is mismatched to the antenna, it reflects some of the energy presented to it and this reflected energy adds to that available for re-radiation.

Fed-ex is fine if you are a business, have a city address, are in the
yellow pages, and have a sign out front. If you do not qualify, it's
just TS.
I live in a rural area- UPS found out how to find us country folk, a
long time ago. The first delivery FedEx tried, they got lost three
times, and I finally had to get them to sit still so I could find them,
instead of the other way.
The worst is RPS- they sent a semi to deliver a two pound package, and
got where they couldnt turn around.

How much vehicle body is there parallel to the bottom of the antenna
and how close is it to the antenna? The large magnetic field at the
bottom of the antenna may be coupling to the vehicle body.

REALLY? Have you ever run the commonly used mobile antennas like the Screwdriver or Hamstick/Hustler
thru any of the available antenna software to investigate their theoretical efficiency - or more
importantly, a good antenna shootout or side-by-side comparison with a well refined custom setup?
I'll put my 90% efficiency homebuilt 20 meter monobander up against anyone else's out there - sure,
a few other custom jobs WILL beat me, but mine will outperform the VAST majority in common use! I'm
not attempting to "reinvent the wheel", only trying to apply well established antenna fact and
theory into an antenna that will truly operate in an efficient manner... And that's what ham radio
is all about, finding a BETTER way, or adapting and improvising in order to obtain best performance
and efficiency from a given system.

Using 'standard' masts,
> coils, and whips, you should be able to put together a 40 meter
> mobile antenna very easily.

Sure, and you WILL make contacts with such a system - just as you'll probably make a few with a wet
noodle in a windstorm - but we're ony kidding ourselves if we suggest standard, off-the-shelf stuff
is the best and most efficient method available to us.

> When you say you want 70% efficiency out of a mobile antenna,
> I'm afraid you dreaming...

I'm afraid, given my parameters, you are probably right - at least for 40 meters and lower bands -
but I'll keep trying - and at least may do better than what is commercially available. I already
have Hamstick and Hustler monobanders, a Don Johnson Screwdriver antenna, an SGC autotuner, and
several other such commercial jobs - but the BEST antenna so far, and BY FAR, is the hybrid Hamstick

mast/Texas Bugcatcher style center loaded coil and 5 1/2 foot whip I currently use on 20 meters with
an extended base section - I'll put that up against ANY "standard", commercially available monobander currently available...

NOW, if I could just do as well on 40 meters... :-)

Get some flat braid cable about one inch in size and connect that from the base
of the antenna to the vehicle body.
What you are describing is a common problem with many mobile installations.

Gary, if you havn't already done so, download program LOADCOIL from website below. Choose coil dimensions and slide the coil up and down the antenna to find maximum efficiency. The program automatically adjusts the number of coil turns to resonate the antenna to your chosen frequency at whatever height the coil may be.

To reduce coil loss increase length of coil to enable thicker wire to be used.. Or increase coil diameter to enable thicker wire to be used with fewer turns. Or both.

You may find for an antenna overall height of 11 feet, at 7 MHz, and a big coil, the best place to locate the coil is, mechanically very conveniently, at the bottom.

Or it may occur that although maximum efficiency occurs half way up, the loss in efficiency by placing the coil at the base is so small that the disadvantage is more than outweighed by the mechanical conveneience.

In any coil loaded antenna design the last thing to decide is height of the coil for maximum efficiency. The program will allow you to experiment with a very long, small diameter coil - a helix ! But at 7MHz you will probably end up with a shortish, fat coil wound with quite thick wire or even copper pipe. The program will allow you to suck it and see before obtaining the materials.

There is seldom any advantage in placing the coil in a short vertical at a height greater than 50 or 60 percent of overall height, especially if a good ground connection is available. With a very good ground the best place is always at or near the bottom. If it's at the bottom consider locating it inside the tuner box inside the vehicle.

Don't be surprised if your pre-conceived ideas have to changed. If you set yourself a very high efficiency target you may end up with a coil former the same size as a 50-gallon oil drum wound with 2" diameter copper pipe. ;o)

In addition to program LOADCOIL you may find programs HELICAL3 and VERTLOAD interesting.

With a ballmount, it is important to ensure a good bite into the metal car body so that both ends of your coax are well grounded.

It is important that the coax is perfect.

You got a 1.6:1 SWR on 10m with an 8 ft whip. Remember that the 1/4-wave whip may be resonant and have a drivepoint impedance of 25 to 30 ohms. You are connecting it with a 50-ohm cable. Don`t expect a 1:1 match. The SWR can`t be helped without a network at the whip for a better match. but the radio match may be improved by changing the cable length.

Best regards, Richard Harrison, KB5WZI

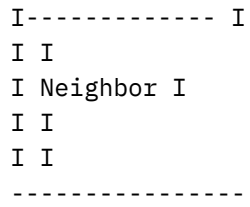
> 73's
> Richard Clark, KB7QHC

Someone on another board that I have been asking about suggested that
I might have short range magnetic interferrence to my TV.
Last night I tuned up on 20 meters and set my keyer to send out a
beaconing signal so I could step away from it and look out the window.
I peeked across the lawn at my nieghbor's tv (which was on) and
didn't see anything unusual from about ~80 feet away. I was only
putting out about 20 watts, and my tv was flashing on and off.
I'm wondering if this is just a short range thing to my own tv, and
the problem may not show up next door? I guess I should try it with
50 watts or something higher, and see if it shows up next door. I
guess if it's clear, I'm good to go.
I live in kind of a T-shaped building. Kind of looks like this (if
this comes across right) Looking down from the top.

```
-------------- ---------------
| Pation | | X Patio | The 'x' is my Isoloop
location
--------------------------------------
I I I
I Neighbor I My Unit I
I I I
--------------------------------------
I I
I I
I Neighbor I
I I
```



So my main concern are the 2 adjoining neighbors behind me and next to me. all the units are 2 floors so I just have the coner shared with neighbors.
The other units are across the lawn and across the parking lot.

Thanks again for the ideas!

Tom KA7VIK

Here is my experience with FedEx

I oerdered a 2.4 Ghz grill type antenna for AO40 from a firm in the USA (I live in Cyprus, East Mediterranean). The dish cost $129 and FedEx shipment $162!!. I don't know how I missed this on the proforma, nevermind. It was shipped very soon after payment apparently but after 2 weeks I had not received it and I was about to write an email to the sender when I received one from them telling me the antenna was returned because my address was wrong! I faxed them a copy of the order with a correct address, turned out to be a typo by them, typed my street as Freakon instead of Feakon!

Eventually they sent it back to me with no extra charge but how much would it cost local FedEx to call or email the sender about this so they could tell me to pick it up or call them? Utter irresopnsibility and disinterest by the employees is all I can think of.

Data Post (express mail) always works best for me.

==========

Gary, I couldn't agree more!

So I feel extemely guilty about computerising the whole business and then cloning and giving away the tools. It reduces the many enjoyable months of experimenting in the workshop, shack and vehicle, the never-ending search for makeshift materials, throwing the results onto the ever mounting junk heap, to an hour of shoving numbers into a software program via a keyboard while sipping California dry red and nibbling potato crisps (UK equivalent of pretzels).

Sad to consider I have become obese and strive to obtain some intellectual satisfaction at other people's expense. Is that progress ?

Regards, Reg. G4FGQ

Actually, you don't need a business address for Fed Ex.

Fed Ex now has a ground service that I've been using for a couple of years. Haven't had any problems with it at all, and it's a heck of a lot cheaper than UPS.

Several years ago, when I owned my own business, I had UPS deliver some C.O.D. packages. I made a mistake and paid for them with cash. A few weeks later, UPS comes back to me and tells me they lost my check and asks me to rewrite the check. When I explained that I paid in cash, they told me I was mistaken, and demanded another check. This went on for a couple of months and then I started getting harrasing phone calls from attorneys representing UPS. It was a total mess, and ended up costing me several thousand dollars. I agree, I'll never use UPS again.

I just use the US Postal Service. Not always the most gentle, the fastest, or the cheapest but it is the most convenient and reliable. I have heard too many horror stories about FedEx and UPS to want to use them for anything. And at least USPS can truly deliver anywhere in the country.

Ground cannot be overstressed. Many (all?) vehicles have a protective coating on the inside of the body panels which prevents a good RF ground from being formed. Scrape the inside of the panel to bare metal and use big, herky, nasty star washers to make your ground connection. Then do the same thing from the body panel to the frame of the vehicle. I personally prefer a spot of weld for the connection, but most folks buy vehicles to resell instead of to use and are loathe to let a welder next to the vehicle.

The other thing to consider is to recognize that mounted low on that big, metal body there is bound to be some interaction between the antenna and the body. Tune the antenna to resonance on the roof or hood or whatever high, clear surface you can find, then mount it and use a tuning circuit to bring the indicated reflected power down to whatever level makes you happy. Until the coil (or the major radiating portion) of the antenna is substantially above the roofline of the vehicle you will most likely experience little joy.

Hi Richard,

"...except in special cases where the current distribution may be
the same for reception as for transmission."

Or so they say after pages of dense math that barely goes into the
matter of the exception (the simple dipole?), which I suspect relates
to the preponderance of "large aperture" antenna coverage in the text.

Still and all, there is discussion that is freely mixing the two
"basis" of match to support arguments that are thus tainted by the
consequent misapplication. Further, aperture antennas are normally
very large in comparison to simple loops or dipoles and this also does
not freely translate (they are distinct as traveling wave antennas
whereas the dipole is a standing wave antenna). As such, confusion is
not unnatural as you have many countervailing issues disguised as one.

Hi All,

This is far simpler than trotting out Huygen or using Thevenin as a
crutch and was a lesson taught to me in introductory circuit analysis.

Every load is also a source. If the signal impressed upon your
antenna system develops some voltage across a load, that same load is
indistinguishable from a source that replaces it presenting the same
voltage back toward the antenna. [Actually, this is a dumbed down
version of Thevenin, but serves quite well and conforms explicitly to
Kirchhoff's sum of the voltages in a circuit.]

> pretty near 100% will be absorbed.

The problem (insanity perhaps?) is in the definition of
scattering. Non-scattering is defined as the situation
where the EM beam is proceding unaltered. In your example
the beam is altered (it vanishes behind the receiver) so
there must be scattering.

Scattered field is defined as: "outgoing field minus the
field that would be outgoing for an unaltered beam".

Incoming and outgoing fields can be defined by decomposition
in spherical waves. There's no problem with that. It's
purely in the definition of "scattering". In your example
there is field coming in and absolutely no field going out,
but still there is "scattering". Cool, isn't it?

Gary,
Yes, I have run the commonly used mobile antennas you named, both through one of the modeling programs, and from the back of my car. The antenna modeling programs usually show what I've seen in actual use (within reason). Speaking of 40 meters only, you will be very lucky to see something approaching 3-9% efficiency from any of them. (Encluded in that list of antennas is an 11 foot 'BugCatcher' using both the old 'standard' coil and the larger 8" coil, not that much differnce.)
Even using the 'BugCatcher', the efficiency on the higher HF bands is ~well~ below 25% efficiency. If you have a mobile antenna that is anywhere close to 90% efficient on 20 meters, you better patent that thing!
'Doc

I just ordered from Universal in Ohio. I asked them to ship via USPS as I have had problems with UPS as I stated in another recent thread. I did have a RS DX-398 stolen by USPS and the box was returned empty! Just so happened I was in a hurry and didn't insure it. Makes me wonder if an uninsured packages are targets for theft, since that's the only one stolen. I filed a complaint but to no avail. They told me there are some dishonest people working for them. :(

I use a lot of "hamstick bugcatcher" type antennas here. As far a
determining the efficiency, I would need to know the ground loss as a
reference. According to Reg's vertload, my present all band bugstick
on 40m in it's longest form has about 70% efficiency "IF" I had a 2
ohm ground loss. That may be hard to get.
Shows about 57% at 4 ohms . 48% at 6 ohms, and so on. Sure, the
helical windings will add to the total electrical length, but there is
a hang. You are really better of just using the large coils alone as
they will be less lossy than the narrow extra windings. I have two
versions for 40m use. My all band antenna, which is a 5 ft firestick
helical CB antenna which I cut a section out in the middle and added a
large loading coil for 80/40 meters. On 80/40m, the stinger is 5 ft
tall and thin flexible whip.For 30-10 m, I bypass the coils and vary
the stingers to tune. I can also add a 3 ft solid mast below this
antenna.
So I'm at 12 ft for this "extended" version. I also have another 6 ft
20m hamstick which I just add the 5 ft stinger to the top and it works
40m also very well. And I can add the mast to it also for 13 ft total.
Either one works like a hose and the 2nd antenna has no large hi-Q
coil at this time. I may add one later and strip off narrow windings
to further improve it. But it works great as is.
I don't know what my ground losses are, but on 40m I've NEVER had any
problem talking to anyone. In fact, from Houston to FLA at night, my
mobile is louder than my home dipole at 40 ft. We tested this many
times from here to JAX. In the day, I always get good reports. Usually
S9 plus to most, and I never run an amp. So my antennas for 40m are
about the same as what you use on 20m. I do have a bit of helical
winding below the coil, and 2 ft worth above the coil, but on the low

bands I don't think it amounts to a whole lot of inductance. Maybe some though as it's above the coil. I've found the best way to boost efficiency is by raising the coil up with lower mast. The difference is quite large. If I run only my 8 ft antenna on 40m, and had a 4 ohm ground loss, my efficiency is about 35%. Just by adding that lower 3 ft solid mast and leaving the rest the same, I jump to 57%. Now if I left the base as is with the coil about 2 ft above the base, and then add 3 ft above the coil, I only jump up to 47%. So you can see it's best to add below the coil. The best place to mount the coil in most cases is about the 2/3 to 3/4 way up the antenna. Reg's programs will tell you the best place. So for me to get the most bang for 11 ft, I would use about a 6 ft mast, a good high Q coil, and then the rest whip. I wouldn't worry too much about the narrow helical windings such as a hamstick mounted on top. You would be better of with a regular hat, not narrow winding/lossy inductance.
All inductance should be had with the less lossy hi-Q coil. So I'd stick with plain stinger whip above the coil if no hat. So to sum it all up, the best 11 ft antenna bar none, would be a regular old bugcatcher with a TALL lower mast, good 3-4 inch or larger coil, and the rest whip. In my lowly opinion anyway...MK

I might add that for my preferred antenna being the bugcatcher with a tall mast, adding a capacity hat would be the best for ultimate performance over using a another narrow loaded whip. So the "ultimate" super duper 11 ft antenna would be the tall 6 ft or so mast, hi-Q bugcatcher coil, and a capacity hat and stinger. I can see no other practical antenna beating it. It's alway better to use more capacitance above the coil than more inductance. If you add narrow wound inductance, you are taking off hi-Q lower loss windings and replacing them with higher loss windings higher up on the antenna. No bueno...:(MK

I have had ongoing problems with swr on my HF6 and now seem to have fixed those by proper grounding. I get anywhere from 1.6:1 on 40 and 10 meters and 1.9:1 on 15 meters. 80 meters I get a 1.9:1 on a very narrow frequency when measured at the antenna.

I am using 35 feet of RG8x as transmission line. measured from the feedline point my swr is 1 point higher. I have tried an RG8 AU with the same readings.
The HF6 directions say to use a 11'2" length of 75 ohm transmission line connected to any 50 ohm coax. Friends of mine say that shouldn t make much difference in efficiency.

What are my likely problems here? I don t want to use a tuner if I don t have to use one. Is that 75 ohm line going to make that much diference? Instructions say that line is for matching in the 10 meter band.

Why 75 MHz?

Why not a higher frequency? The antennas would be a lot smaller and
they may allow directional antennas.

Correction: the 75 ohm line to be connected to any length of 50 ohm coax.
This antenna is on the ground with 24 radials ranging from 16 feet to 25
feet. Antenna is 26 feet in height. Kenwood 450S @ 100 watts.

Sounds good to me. George W. needs to switch to the UK equivalent.
Actually, potato crisps are probably a substitute for the pretzel for
which our Pennsylvania German communities are famous.

The UK crisp is called a chip in the US. The UK chip is called a fry, or
French fry, in the US. One of the joys of patronizing a McDonalds in
England was not being asked: "Do you want fries with that?"

I have installed two ground rods over the years and they both have been eaten away to a small spike in just a few years. These were copper cladded steel rods. I was recently told that a pure copper rod won't be affected by the chemical reaction. I'd like to use a 3/4 inch copper pipe, but driving a 10 foot length into the ground is a problem, especially with some clay in the soil. While a copper pipe is fairly rigid, it won't withstand a sledge hammer. I'm looking for solutions to accomplish this task.

I checked out http://www.rayfield.net/isotron/ (i.e. the Bilal Isotron home page I think)

This thing looks interesting. Kind of reduces the whole antenna+tank problem to it's essentials. Do the magazine reviews and promo text on the site tend to understate it's directional characteristics? Have you fooled around with one yourself?

My first impression is that there's a lot of theory at work here and Mr. Bilal probably spent many hours with a calculator before he built the first one. It can't possibly be as easy as finding the right size, shape, etc for two (capacitive) plates, mount them the right distance, orientation, etc inside an aluminum tube, then connect a "dual duty" inductor/radiator coil of suitable design between them and couple in the feed power (one way or another). Generating an RF beam like this sounds too good to be true/easy. In the past I've found this means it isn't/isn't. Have you ever seen something like this in action?

Great pointer, thanks,

Mike

Use a shortwave receiver, and note which WWV signals you can
get...don't forget to check for noise in that range.

>Are there any other factors I should look for? More importantly, are
>there red flags to watch out for?

Built-in dimmers - even if you don't use yours, it's going to be hard
to stop the neighbors, and you won't hear their RFI during the day, so
it's hard to check for. Don't count on any apartment complex going to
the extra expense of using good ones, either...I've been thinking
about keying and tuning our dining room dimmer to see if I can get
some CW contacts from other galaxies.

JLB <jim.bolinger@lintek.aeroflex.com> wrote

> Why 75 MHz? Why not a higher frequency? <snip>
> Jim
> N8EE

The real problem with changing frequency is the clock signal which is being transmitted at the same time from a quarter wave vertical on the top of the receiving small loop array. In a sentence or less - The two signals (Clock and Object) need to be related in frequency such that the clock interval undersamples the object wave to produce an alias "wave" when the sample stream is considered as sequences of n samples. OK two sentences - This requires that the ratio of the two contain prime factorizations with a limited number of commonalties. To make a very long story short, the best combo is 27.198MHz and 75.55MHz with a backup pair at 27.1476MHz and 75.41MHz. This way I get a 25:27 ratio and a 9 point alias wave being generated from each of the four points of the receiving tetrahedron (i.e. pyramid shape) for phase analysis by the DSP. The 27.1476 is an allowable 2600Hz off channel center and the 27.198 is an allowable 3000Hz. If I can solve the transmitter directivity problem I think this is where this thing belongs . Everything in bands designated for remote control (by Joe Q. Public and his kids).

Well, while they're hardly the match for some of the pricier models,
I've got a RS DX-398 (rebranded ATS-909, $150) and a DX-398 (rebranded
ATS-818CS, bought used for ~$100) here in my apartment, and I'm using
metal raingutters for an antenna with fair-to-good results for both
shortwave and AM broadcast band DX. Due to the electrically noisy
conditions, (apartment, and KRLD's 50kW signal nearby) and the strange
nature of the antenna connections, I had to build a good preselector
for them, but that's a one-evening, under $10 project.

Ground rods make very inefficient radio ground electrodes. They are no
better than buried horizontal radials of the same length.

Save yourself the trouble of driving more rods by laying half dozen or more,
20 or 30-feet long, shallow-buried radials. You will probably notice a
change for the better.

what you are describing is basically using the isotron to drive an open ended waveguide. the pattern will not depend on the properties of the isotron but on the size and shape of the tube. open ended waveguides are generally not very directional as the waves generated by the fields at the open end are much like simple dipole fields. a tapered horn of the proper size and shape will provide a much better pattern, maybe exciting with the isotron will provide enough loss to keep the gain down, but a short monopole or loop probe is much simpler and easier to control.

Hi OM,

Why use a third party shipper like those stores ?
Pay the fee and call them for a UPS Pickup and you are using UPS
(or fedex or usps whoever picks the box up)

by using these 'authorized centers' you are under their thumb if an error

is made. Lost or damaged, that third party shipper has to file the claims

with ups/fedex/etc. not you because you are not shipping the box, the
third
party is shipper and selected the carrier ups etc.

Another tip, if you are buying an item from someone either on auction or
swap, do not let the seller ship the item, call UPS or FEDEX and have the
go and pick it up by using the call service. small fee BUT big
difference..

you are now the sender and you can file the claim if lost/stolen/damaged.

otherwise, you are under the thumb of the seller and only seller can file
the
claim with carrier.

Very complicated but once learned you can have your packages arrive !

Cross-posted to: rec.radio.swap,rec.radio.amateur,rec.radio.scanner,rec.radio.shortwave,rec.radio.amateur.antenna

While I suppose there is a first time for everything, I've yet to have a problem "with UPS" - myself being a shipper. As for the others, I've had items delivered to me from shippers via Fed Ex, but not RPS. Not even sure if RPS is doing business in our immediate area. I've sent light and heavy items via UPS and never yet a problem or complaints from the receiving parties of any.

Two problems I "did" encounter.....

1. A package that was allegedly shipped and I never received it. NOR did my UPS delivery man recall it. According to the shipper of the item, the item was taken to shipping site. The package and ALL paperwork then disappeared. The tracking number supplied to me at drop off, kept showing "not a valid number". Assuming the shipper did ship it, which I had no reason to doubt as I dealt with them before, sounds more like a clerk problem to me. Though it did take a few weeks to get my money/items replaced, I can't say for certain whose fault that was..... as to the delay to conclude it. Could have been a delay in shipper to start the investigation, the shipping site to do their own investigation. I don't know. All in all, it wasn't too unreasonable an amount of time once I knew "something" was being done about it.

2. Around here, there used to be a few UPS shipping sites. Most stopped taking UPS.. (Mgmt changes they said) Down to about 3 sites within reasonable travel distance, two of them were reasonable in cost both small and large, even with
the site's service fee included. The third was ridiculous.

At the 3rd, I paid as much to send a small box out - as a box 25 times bigger than that - previously from one of the other sites. The other sites are now shut down. I think the 3rd shipping site was over charging on the service fee. I'm not aware of what they are allowed to charge for their fee, so I had no way to challenge it. I suppose I could have said forget it, but the clerk wrote it up before giving me an exact total INCLUDING their fee. Not wanting to look or feel like an idiot (cheap or confrontational) especially without facts to support my claim, I decided to swallow my pride and to let it go this time. But, I've yet to go back. I've been shipping primarily Postal only for that reason - unless I happen to be going near a different site which is a distance away from me.

Now I have to use the charts online for UPS and Postal to get the best rate for the individual package. Personally, I still would prefer UPS. And, if I AM going out and about, I will make the trip to the distant UPS site....

Unless some one can prove to me beyond a shadow of a doubt - otherwise, I don't believe the UPS service itself in any way, was responsible for the two

episodes I experienced.

My company (TFW Inc) has stopped using UPS for similar reasons.

We were receiving a %20 lost shipping and damage rate.

All packages now go thru USPO Priority. Not a single failure in the last 300 ships.

You should have checked old messages within these groups, we have been
talking about avoiding UPS for YEARS!

For packages such as the one you describe, there are other very good
alternatives such as Osborne Air Freight who want to do a good job.

Welcome to the "piss on UPS" crowd.

Some new stuff has been added at www.ab7sl.com in the past few weeks....

1. Site search - the entire site is now indexed and searchable from the
homepage

2. Arizona Repeaters Page - covering all repeaters statewide
on ALL bands. This added some 20 pages to the site.....

3. Weather Page - shows temps for selected US cities , full weather
conditions
for Prescott,AZ and USA - World weather maps and forecasts...

4. Added a Grand Kids Photos page....they are so cute and adorable!

Amen. Driving around town, there are two places I can always count on picking up QRM. One is near a small ISP, the other is near the University of Michigan's Computer Science Department. Both places can completely obliterate a major local station on by car *FM* radio! There are apartment complexes near each of these locations. I've always wondered how bad it would be to live in them.

On a related note, is there any way to force a computer installation to reduce their spurious RF output? I won't hassle the University ("...the hand that feeds you" and all), but that local ISP kinda ticks me off. They're not even all that big a place. I envision some out-of-date computers overclcked and with the cases removed to help cool them.

Hi Joe,

For what is worth, the additional expense really goes into features
more than sensitivity per si¿½. One such feature is the BFO. My
DX-440's BFO is rock stable, although that may not be true for all of
them. Then there is multiple conversion and filters that jack up the
price. However, this says nothing of sensitivity when TRF radios can
do just as well, or those designed around phase quadrature detectors.

>Joe Bramblett, KD5NRH

Hi Joe,

I have dimmers installed at every light switch, and yes they do
generate quite a hash.

However this more a problem of conduction than radiation. I soon
discovered I could run my dimmers indiscriminately for casual
listening if I separated their power paths (the dimmer being on a
separate circuit from the receiver). For DX it did come in through
the antenna port, but then I simply moved the antenna feed point
further away from the house, snubbed it with ferrites, and went on
listening.

The radiative path is one of luck (bad) when house wiring is of a size
to become resonant. Electric fences that complete a loop are
especially bad in the "quiet" country side (and sometime a source of
greater grief than living next to a neon sign in the city).

WELL Doc, I'm not too certain as to the accuracy of indicated efficiency as obtained from readily
available mobile antenna programs - I suspect they primarily are just good places to START playing... But I *DO* know that the operational efficiency of my 20 meter mobile setup is VERY
equivelent to my 20 meter inverted V antenna at 70 feet - and only about the expected S unit less
than my Mosley Classic 33 beam at about the same height - proved that MANY times, with MANY stations
all over the US... SOOOo, with THAT in mind, I don't feel TOO uncomfortable in accepting the 90%
efficiency figure the modeling program I was using stated my antenna was capable of...

AHHhh, but 40 meters, my OTHER primary mobile band will be a MUCH tougher challenge I'm afraid...

I don't know if it will work for a copper pipe, but I drove down the
grounding rods by first punching it into the ground and then wetting the
area. Then punch again and then go up and down with the rod like a plunger.
When you aren t making more progress fill the hole with water and keep
plunging away. It works. But a warning: Don't stop. I was halfway down with
a rod and was overtaken by a thunderstorm. The next day, I went out and the
rod wouldn t budge. Had to pound it the rest of the way down into the
earth.

OH, for you and Reg - I wonder if there is any program or table showing or computing the effective
additional electrical length of a capacity hat added to the top of a mobile whip?

For instance, if I fabricate a simple "X" capacity hat from a pair of 3 ft long 1/8th inch brazing
rods, and attach them to the top of a 6 foot stinger on a 20 meter monoband antenna, how much
effective length have I added to the overall whip section?

How do I find out, other than tedious cut-and-try?

Hi Doc,

Did you model a helical antenna with hundreds of turns
in NEC? How many elements did the model have? Just curious,
not questioning your veracity, but I have tried it and I
needed like 10 or so elements per turn and even at that I never
got anything that was consistent--the results changed de-
pending on how many elements I used. I was modeling a 40 meter
radial mode helical over infinite perfect ground.
Is there a lower limit on element size for NEC2?

Hi Francesco, Stefano,

This indeed marks progress. A good source of such methods is found in
the antennex's critic and noted authority, Jack Belrose. You would do
well to examine the photographs which clearly show the care of
removing the measuring equipment well away from the antenna, and
performing the tests in the most non-reflective environment short of
lab.

Please keep us informed of all development.

I'd like to use a 3/4 inch copper pipe, but driving
a 10 foot length into the ground is a problem, especially with some clay in the soil. While a copper pipe is fairly rigid, it won't withstand a sledge hammer. I'm looking for solutions to accomplish this task.

Attach a fitting that will adapt to a standard garden hose. Attach the pipe with the fitting to the garden hose and the garden hose to the water supply. Turn on the water supply so that the water is coming out the end of the pipe. Stand the pipe up on its end and start pushing. The water should dig the hole for you and allow you to slide the rod into the earth.

Rest assured, when it gets to Colorado, it will
> not have passed through UPS hands.

Having said that I, too, would not use UPS, I have broken my word quite a lot! Most of the
Carolina Cyclone antennas I build and ship go out UPS. I use PVC pipe for shipping containers, and that has proven to prevent the breakage they are so notorious for. I used to
get lots of broken coil covers, either by simple mashing, or slinging them on and off trucks. By
using plenty of packing material (bubble wrap, newspaper, etc), I've had pretty good results so
far (knock, knock).

When I worked in the rail industry, I used to ship as many as 20 packages per day. What got me torqued at them was the time I carefully packaged a boiler water sample, cushioned the plastic jar with several layers of bubble wrap, and put some foam sheet on the top. The package came back marked "improperly packaged". The kicker was, it wasn't even the same
box I shipped it in and all that packing was missing! I called them and received the "Yeah, right!" treatment from the rep, and I went ballistic. With quite a bit of invective, I explained to
the smart-assed lady that the box wasn't even in the same SOBing box I shipped it in. I got
pretty sassy (putting it mildly) with her! Finally, I told her, "Tell ya what, lady. You pull your
records and see how much we ship with you. I happen to be the one that decides who I am
gonna use, and YOU don't tell me what box I shipped a package in. And from now on I will
use Fed Ex. YOU can turn it crossways and shove it-- I don't give a ****!" I started shipping
via alternate shippers, and I guess UPS sort of "missed" our volume because it wasn't long before one of their suit and tie types was in my warehouse wanting to know what happened.
I had the chance to tell him, of course, and a chance to get a jab in at their customer service,
telling him about how their smart-mouthed lady was "able" to tell me what carton I shipped in.

He, too, was a little upset when he found out that they had switched boxes on me. It took a
lot of promises and begging and several visits from the customer rep before we shipped with them again.

If they pull a caper like that again on me, now that I am running my own business, it'll be a cold
day in you-know-where before I ship with them again.

But after you do this, the pipe is typically in very poor contact with the remaining soil. For this to be an effective ground, the hole around the copper must be backfilled with one of the conductive materials used for this purpose. I know the name "Bentonite" to be one of this class of materials, but have no idea what it is or where to get it. Driving a rod into earth compresses the surrounding soil and leaves the rod in intimate contact, a condition not usually achieved with the water method.

You may be right. I assumed that the water would actually break up the soil around the rod and actually help compact it against the rod. Maybe not.

Go to the local pet supply shop and get a bag of the cheapest clay based
kitty litter there is. It is usually very close to being 100% bentonite.

1640. Re: NO MORE UPS FOR ME / Rant / Long

To add more lunacy to the ranting:

I used to own a small computer business and had to have some parts shipped UPS red (overnight) from Seattle, Wa to Waco, Tx. The next day the package did not arrive, so I called my supplier who said the shipment went out with the other overnight pickups at 4pm. We checked the tracking # supplied, and it shows that the package never made it to the first checkpoint, but WAS picked up. I had a good supplier, so they overnighted me the part again and I received it the following day. Here's the gripper though....about 1 week later, a VERY confused FedEx employee walked into my store with my package. It did not have any FedEx shipping credentials on the box, just the UPS shipping labels and my address! The driver did not know how the package made it anywhere with UPS suff on it in the FedEx system, much less how it ended up in his truck for delivery.....all we can figure is that UPS and FedEx were at my supplier's dock at the same time and my package went with the wrong carrier....

Go figure...

Bentonite is used by well drillers to form an ecology seal around the casing to prevent surface water intrusion into the acquifer.
Most well drillers should be willing to sell or give it to you at a low cost. It is a fine pulverized clay.

Copper sulfate is mostly used to provide a good ground contact.

another suggestion is to use a hammer-drill for driving ground rod. Here in the Pacific Northwest we have a lot of hardpan and rocks in the soil and I have successfully driven 8ft rods using this method where the sledge hammer or slide hammer fails.

Gary, download program TOPHAT1 which helps design short verticals of height H surmounted by a set of N radial rods of length L.

The antenna has no loading coil in it. But in effect it is 'bottom loaded' with a coil which may be inside the vehicle - a part of an L-match tuner. The program calculates tuner inductance and capacitance values.

With top capacitance loading it doesn't make much difference where a loading coil is placed in the antenna. So for mechanical convenience place it at the bottom - inside the vehicle. The advantage of having the coil in the antenna is that it can be physically larger and therefore of higher Q.

If the coil is actually in the antenna I would prefer to place a coil about halfway up the vertical. There is then a better distribution of top-hat capacitance between ground and that part of the antenna+vehicle below the coil. At half height, coil inductance will be a bit bigger than when the coil is in a bottom-end tuner. The program doesn't calculate inductance for heights other than at the base.

Top capacitance loading is superior to coil loading because -

(1) it increases radiation resistance more than coil loading simply because it can be placed right at the top, whereas a coil turns into a dummy load when it is placed near the top. (Extremely high inductance and very low Q due to self-capacitance).

(2) There is negligible conductor loss associated with a capacitance hat.

(3) With a capacitance hat, a smaller loading or L-match inductance is needed and so, for the same coil Q, the coil loss resistance decreases. As a by-product the program estimates the difference in dB between capacitance and no-capacitance loading for a given set of antenna dimensions.

There's a BIG disadvantage - to achieve the above benefits it is necessary to have a top hat diameter equal to antenna height. This is more appropriate for a back yard than a vehicle on city streets. And in a back yard performance can be improved much more economically and conveniently just by doubling height.

Program TOPHAT1 does not calculate the equivalent extra height of N radials of length L. But you should be able to estimate it from the behaviour when L is varied with N fixed, and when N is varied with L fixed. Capacitance is approximately proportional to radial length and to the logarithm of their number.

Incidentally, you'll notice there's not much point in increasing N beyond 16 or 32, there is hardly any further increase in capacitance. Which is similar to what I've been saying for years about buried ground radials - ground loss resistance does not decrease significantly beyond 16 or 32 radials. Any more is overkill. Yes, I've heard about BL&E ;o)

Download TOPHAT1 from website below -

Hello John,

George said practically all there was to say about it with the limited info
you provided.

But if you like I'll repeat it.

There's a tapped coil with tuning capacitors across it. This is a classical
arrangement for matching end-fed short wire antennas to 50 ohms or what have
you. It will also match other high impedance antennas such as long wires,
an integral number of half-waves long.

But with the double-tapping for input and output it will match almost
anything to anything provided its not too extreme.

You seem uncertain about the number of vacuum-variable capacitors associated
with the coil. Draw out the full circuit on a piece of paper and you should
see what it is intended to do. Is it switchable into a Pi-network ? Is it
switchable for balanced output ?

With that size of coil it should handle 160 and 80m band antennas quite
well. A nice job. It would be shame to modify it. If you don't want it
ship it to me.

Reg G4FGQ

Something that most people don't know about is that the radiation of
mail to eliminate anthrax WILL destroy electronic equipment and part.
There is a somewhat benign warning on www.jedec.org.

Bottom line, don't use the Post Office to mail electronics to zip codes
that begin 202 through 205.

Many of the parcels I deliver for the US postal service are ones that the sender and probably the recipient wanted to go fedX...but fedX remailed it to save themselves a trip.Might as well use the postal service to begin with.

Use a fence post driver available at most hardware stores and the ground rod drives in easy.

I understood that back in early September the USPS had started using Fedex facilities for moving some Priority and Express mail. My own delivery times took a nose-dive then and have just gotten back to normal since 9/11. Had a (another) Priority package arrive in less than 48 hours just the other day from my remote QTH (offshore island of Puerto Rico) to a town in the Midwest. Amazing.

Message-ID: <DWl48.13142$TI3.129067@typhoon.sonic.net>
Source record: 150140

Recently I came across a 1000' spool of wire I had always intended to use to build a T2FD with but never got around to erecting the supports. Wanting to get my shortwave (AOR 7030+) fired up, I decided to throw up a beverage. I figured it would be a waste of time but thought I should at least be able to hear something. The reason I was pesimistic is that my house sits halfway up a 1000' hill. Here on the west coast (USA), shortpath to just about anyway is north and the peak of the hill is due north from my house. Not to be confused by the facts, I strung the beverage up anyway, running it up the side of the hill which averages about a 25 deg. slope. I wound a 9:1 balun, drove a couple of 10' copper stakes in the ground, layed out a few counterpoise radials, terminated the far end (at the top of the hill) with a 470 ohm resister and called it done. In the two weeks since I've had it up I have been absolutely amazed at the results. I can consistantly listen to Middle Eastern stations (KOL, Kuait, Egypt, UAE) 5/9 and Southern Africa 4/7. I am working these over the Artic Circle as verified by the 25 dB null I am getting to South America when I attach the end termination. This morning I pulled in Makassar Indonesia which runs only 25 kW.

Does this surprise anyone but me? I would think the hill would shade all the low angle radiation coming from the north. Isn't my effective angle of radiation something like 50 deg? (25 from the hill anfd 25 from the antenna). Whats up with this?

Not complaining, just curious.

GEEZE, I hate to be asking so many questions (but how ELSE to learn - or display my ignorance...)...

I have found that there is a pronounced observable change in loading of a mobile whip/capacity hat
when the capacity element is moved up or down on the whip portion of a center loaded whip (probably
true of ALL whips...). Sometimes it SEEMS that substantially LOWERING the mounting point of the
capacity hat has relatively small effect on the overall tuning and performance of the antenna as a
whole - sometimes I have even mounted the capacity hat immediately above the coil, with results
nearly as good as up near the top of the whip.

Any comment?

1656. Estimating ground plane efficiency -- a confession

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-25 23:51:40 UTC
From: zygo@azstarnet.com
Message-ID: <zygo-2501021651420001@10.0.0.2>
Source record: 150143

In article <zygo-2401020859040001@10.0.0.2>, zygo@azstarnet.com (Jim Mandaville) wrote:

> I'm trying to estimate as closely as possible the efficiency (pwr radiated
> over pwr delivered by feedline)
> of my 14 MHz ground plane.

I thank all for their comments. I'll now make a confession to explain why I was asking about something seemingly of little practical importance (as at least one responder gently hinted :). I can, after some trimming, use this antenna on 14 MHz. It is now resonant, however, on 13.5 MHz, where I'm using it for a Part 15 beacon, the output of which is regulated by FCC rules. The rules allow me a field strength of 10,000 microvolts/meter at a distance of 30 meters from the antenna. A rule of thumb among the small group of people involved in such "hifer" beacons, is that this will be produced by a dipole fed with 1.8 mW (many settle for 2 mW). At first I was not sure where this number came from, whether from someone's empirical measurements or from calculations. Although I'm a non-engineer with sub-calculus math I decided to take a stab at such a calculation with the help of a couple of references and amazed myself by actually coming up with the same power level (after allowing for the 2 dB difference between a real dipole and the isotropic of the calculations). It struck me, however, that this assumes an antenna with 100 percent efficiency. To produce the given field strength, one has to increase the power to make up for any inefficiency. Thus my concern for that factor.

In short I'm trying to produce the maximum allowed field strength by setting my transmitter output power to make allowances for my 0.2 dB transission line loss, the 0.5 dB gain difference between a dipole and a ground plane with drooped radials, and the efficiency figure of the antenna itself. (Using 90 percent as the efficiency, along with those other losses, I come up with a need for 2.3 mW into my feed line to do the job). Measuring power at such low levels is not a simple thing, but I've

got two independent means to measure it to 1 percent accuracy.

Probably the majority of such hifer operators are not all this concerned with power accuracy
at this low level, but I just considered it a technical challenge that would be amusing to deal with.

By the way, I'd love to have any reception reports of my beacon, which runs 24 hours a day on
13.5545 MHz, repeating its CW ID "AZ" at 12 wpm. So far it's been heard in Texas and at three
places in California.

Cheers, Jim Mandaville, Tucson, AZ, KF7A

Well, I regularly hear Kuwait and Bangalore, India on my 1940 Hallicrafters with an indoor antenna 15 feet long. I'm not sure how to report the signal strength, as the SX-28 has a rather squirrely S-meter. But it's quite good copy at grey-path time. So I guess I'm not surprised. But did you string out the whole one thousand feet?? Don't reel it in. I've never used one but hear it can do good things for you at lower frequencies.

I've not used an L-C circuit like this (in a tube) but I have used a
simple stubby rubber duck in a tube at VHF and UHF at reduced power to
achieve results much like you say you want. Try it, it just might work
for you. My L-C suggestion was merely an attempt to get you thinking in
terms of a reduced size radiator instead of a normal 1/4 wave or
variation thereof.

I've read all the other threads to date - thanks!

On the Ford Explorer, on the rear left side, about 2-3 inches below the left rear quarter-panel window, there's the ball.

There's very little metal between the antenna and the rest of the vehicle - there's only about 2 feet of "car" and the rest of the antenna is well above the vehicle.

Ground is good. If you use a VOM and just look for a dead-short - you have continuity between the base of the antenna / coax braid connection and another good strong ground point on the other side of the vehicle. It appears that we have good ground. I could be mistaken.

I probably need to get some digital pictures together so you guys can eyeball the installation to see if you see anything funky.

Hi Jim,
Thanks for the response.

Bangalore is a 500kw powehouse and Kuwait (200 kW) beams to NA. On 45 meters, I'm picking up African, Chinese and Russian regionals, Myanmar (50 kW Indonesian pointed sideways from me) etc. Other west coast SWLs are green. Take my word, this antenna rocks.

I used 950' wire to get to the top of the hill. Didn't start down the other side. One thing that I've noticed is this antenna is much quieter than the 100 foot longwire (60' high) I used to have.

I guess angle of radiation isn't that important for reception?

A friend and I just put up and evaluated the new Cushcraft minibeam with capacitively loaded elements. Nice front to side and very surprising front to back. Much better then that Butterworth (or whatever) thing. Looks nice on a mast, very low profile. Quality construction and solid engineering. SS hardware as well. Good swr bandwidth but not great (To me this means high efficiency and high q) The tuner in your rig will get you to the band edges but for other than 20 it covers most of the band anyway. Of course my fiend would love to sell you the Mrs. Butterworth. hihi That thing has so many poor connections it's practically 50 ohms resistive!

How about cutting the ground end into a wedge and sharpen it then drive a piece of wood into the hit end then slam away. Cut off the wood end when it's driven all the way.

Reg
Thanks for the reply, I guessed it would be OK for 1.6 to about 4Mc/s as it's designed for HF navigation apparatus and I think it's part of a mobile system so a short vertical is probably a good guess. The circuit is exactly as I've described - with one or two vacuum variables across the whole coil where the second one is switched in parallel with the first via a chunky reed relay providing a total range of 8 to 1300pF, it's unbalanced in and out and is not switchable to a pi network. The only aspect I left out is that there are direct bypass positions on both input and output tapping switches.
Part of my question was because I've never seen this configuration shown as such in any of the amateur literature so I guess that maybe it's because it doesn't provide any harmonic suppression?, my other concern was that there is no series capacitor on the input to tune out the reactance of the input part of the coil as I've seen in link coupled circuits but my understanding of ATUs is a bit hazy as I've never applied myself to the problem and there's so much written about so many configurations for such a relatively simple task so I'm going to start back at first principles.
I'll just put some RF through the ATU and try it once I've changed the Lemo connectors on it.

Have used the garden hose and pipe trick many times. If you think the ground rod is not in good contact with the ground let is set for a week and try to pull that 8' rod out. If you have the same luck I do you will need a "handyman" jack to get it back out of the ground. Have never had any trouble making good grounds using this system and have a total of 8 ground rounds around the house.

The best device I've found is a ground rod driver that Glen Martin sells (the people who build towers). It's a piece of sturdy pipe that slips over the ground rod. It has a metal plug in it. It has big handles on each side of the pipe. You grab the handles and slam the thing down on your ground rod. Wham, wham, wham, and the rod goes in, sliker'n a whistle. Lot easier to use than a hammer.

John,

Your low return loss (VSWR) readings on the magnet mount and on your vehicle are cause by losses. You're getting a false reading. The high readings on ball mount are more accurate because you have a much better RF ground. A low return loss (VSWR) doesn't necessary mean the antenna is at optimal performance. In fact it could mean something is wrong. Many hams and CB radio operators assume a 1:1 VSWR means everything is fine. That's not necessary the case. You need ask yourself the following questions.

Does this low VSWR reading make sense?

Does this high VSWR reading make sense?

What tells me that the high reading is probably the accurate one is the 8-foot whip. I'm assuming that the antenna was designed for the CB band, a 1.6:1 VSWR is about what you should see on 10 meters. A 1/4 wave antenna on 10 meters is shorter.

GW

Okay, that sounds more like something interesting. I've always wanted to try a really long wire. What's the average height of your wire (for Beverages, it's not supposed to make much difference, I understand).

Have any study been done on this? I'm surprised that the ARRL hasn't researched this. (Or have they?)

I am willing to bet that electrical engineering majors who operate ham radio (or who participate in other EE-related hobbies) tend to do better than their nonham counterparts. I know I would have been a MUCH better student if I had been a ham radio operator when I entered college as an electrical engineering major. Without ham radio (or any other practical experience), SWR, Smith Charts, matching networks, and other concepts were just mumbo jumbo I had to plow through in order to get through classes. It took ham radio to enable me to truly grasp what I studied.

I would expect to see that EE hams, as a group, earn better GPAs, are less likely to drop out or change majors, are more likely to be actively involved in EE-related extracurricular activities (like IEEE and various contests), get better jobs, and are more likely to earn graduate degrees in EE.

I'm also willing to bet that even after one adjusts for differences in SAT scores, high school class rank, and other admission criteria, EE hams still earn better GPAs than their nonham counterparts.

If I were the head of a college or university EE department, I would pull out all stops to recruit ham radio operators into the student body and faculty. I would also work with the school ham radio club to recruit new hams on campus and in the surrounding community.

As an EE who was involved in electrical and electronic stuff prior to going to engineering school, I have to say the previous experience probably makes you a *worse* student, not a better one. The plain and simple reason is that with "a little knowledge" you tend to assume you know more than you really do and that is definitely a bad thing when entering a field such as electrical engineering. Yes it's easier to learn stuff because you already know *some* of it, but it's also even easier to *assume* you know stuff that you don't.

In addition, not all of the training associated with something like ham radio (or any other hobby fields) is kosher, so some of what was learned before studying engineering may well be wrong, or incomplete.

If I was the head of the EE department I'd take people on their merits and not favour them on such inappropriate grounds as whether they've got a radio ham license. If anything it would work against them on the basis that "a little knowledge is dangerous".

My thoughts fwiw.

Around 10'. The two things that seem to really matter are the termination (I used a spectrum analyzer last week to measure the null on a SA station (around 6 MHz as I recall) and measured a 25dB difference with and without the 470 ohm resister) and the ground counterpoise at the termination end. A ground rod (about 6' of a 10' copper clad stake driven into the ground) didn't seem like enough. After I laid out some radials I noticed a marked increase in sensitivity(although the background noise seemed to go up as well). Removing the feedpoint counterpoise didn't seem to make any difference.

If you got the space I think a beverage is well worth a try.

I don't think amateur radio qualifications are worth anything much in
electrical engineering. I decided to enter the exam just for the hell of it.
The night before the exam I read the licensing conditions and got a credit
for that part and a destinction for theory. Quite frankly, it was piss-easy.
I have no other qualifications in electronics, apart from attending an HND
bridge course for nearly a year and having worked and played in electronics
most of my life. I kept my AR license up for one solitary year before I
realized what it was really like ;-)

Depends. If they are like that idiot DaveD that responded that he only did it for the fun of passing the exam, the license has all the worth of breasts on a bull.

If they are like most of us who earned the damned thing in high school and experimented (and got zapped a few times) all the way through graduate school...I'd hire one of those persons in a second over a PhD that never smelled hot solder in their life.

Reminds me of the joke "BS" means "Bull Slop", "MS" means "More of the
Same" and PHD" means "Piled Higher and Deeper".

1679. Mobile antenna installations - question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-26 05:56:11 UTC
From: JG in NY <n1aep@yahoo.com>
Message-ID: <%xr48.6189$Ki1.638330@typhoon.nyroc.rr.com>
Source record: 150167

I notice that a lot of mobile antenna situations involve the whip extending up along the side or back of the vehicle for some distance (esp. with a bumper or ball mount).

Wouldn't this pose problems? I'm imagining that it might similar to taking a dipole and placing both legs in proximity, parallel, even, separated by only a couple inches. It certainly wouldn't be a very operable arrangement, and the impedance at the center would certainly not be the in the usual 75 ohm neighboorhood.

What would be the effects of this type of mobile installation -- on, say, impedance at the feedpoint, or SWR, or distortion of the radiation pattern?

How would it be different from a dipole folded sharply back on itself?

Roof mounted antennas would appear to be the ideal, if practical for the bands in use. The ground plane is perpendicular to the radiator, and below it. Not alongside.

Thanks for any comments...
jg

For an 'amateur' wishing to be and being educated to become a
'professional', the hardest thing to do is to clear the mind of the
preconceived, wooly, technical notions previously acquired, and return to
square one. Otherwise you will be handicapped.

The next hardest thing is to learn to think quantitatively, precisely, in
terms of numbers. If you cannot quantify or measure what you are speaking
about then you know next to nothing about it.

On the other hand, supervised practical experience gained as a radio amateur
during the course of an engineering education is just as valuable as that
gained in the laboratory. But it should not supplant it.

You'd probably find that ham radio has nothing to do with it. Rather, the type of student who really is interested in the field, and probably does well in studies, is more inclined to operate ham radio. I personally have never seen the need to run a ham set, although I used to listen in on a multi-band radio when I was ten years old. I suppose if you narrowed it down a *lot* more, for example look at those engineers specializing in wireless technology, you'd find a better correlation. But I really don't think it was the ham set that did the trick; rather, those most likely to get involved in their studies may have had more desire to operate one.

I always had more of an interest in computer interfacing and stuff. I suppose the parallel would be heavy use of the internet for communicating with others over large distances! :-)

Once again, how about providing a description of how you determined this efficiency?

I can make an antenna more efficient than a dipole quite easily, if I place the dipole on the ground.

> Still today I don't understand WHY very few hams tried to have one built.

We want some valid scientific data - not just a bunch of claims. If the data looks promising, then we would try building the antenna.

There are those that will try anything - even the base loaded tree that was in one April issue a few years ago. But such people are rather rare, as well as probably incapable of making valid measurement of the results.

I'm probably an exception. I was a lousy EE student. I worked my way through engineering school doing circuit design (and with a little financial help from my former employer, the U.S. government), and was constantly frustrated by the huge gap between what I was learning and what I needed to know to solve the real-world problems I encountered daily in my job. The professors had almost no idea of what the real world was like. (Example: In frustration, I asked the head-in-the-clouds 20-something year old PhD math instructor trying to teach us differential equations to help us get connected by solving a simple mass-spring problem. "Masses? Springs?" he replied. "What do differential equations have to do with masses and springs?") A 2.0 GPA was required to graduate, and I felt (and still feel) that graduating with 2.01 was a waste of one half of one percent of my time. I did end up overshooting, but not by much. I had no trouble finding a job after graduating, since while I was going to school I had designed all or a major part of ten production instruments for the small company I worked for. And after the first job, no one cared less about a GPA, as it should be.

About the happiest day of my life was when I finally got finished with the stupidity of that "education".

Later on, from time to time I was called on to do screening interviews of college students for the large company I worked for. Ironically, I wouldn't have qualified for most of the interviews myself, not having the minimum GPA required of the students I interviewed. I've found that GPA has very little correlation to a person's ability as a design engineer. The GPA measures the ability to analyze prepared problems and repeat back what's expected, while design work requires synthesizing solutions, a very different process (which does, however, require analytical skills). What I find to be a much better indicator of engineering skill is curiosity, something not generally encouraged in engineering school. A good design engineer is simply bugged if something shows up that he can't understand or that doesn't work like he thought it did, and will stick at the problem until it's understood. In the interviews, I was much more interested in any kind of hobby activities they did on their own, the problems they had solved, and how they had approached and solved them, than I was in a GPA. And ones I selected who were hired turned out to be pretty good engineers. (They did, admittedly, also have fairly high GPAs, that being required to get the interview in the first place.) I saw plenty of students with a 4.0 who would have been disasters at doing design.

I'd say that the hams I've known who are design engineers have, on the average, been among the better ones. But I don't think they've necessarily been the best students. I think it would be great if universities would hire more people who had some experience with reality. But then they'd have to pay 'em. . .

Paul,
No, I didn't model a helical antenna like the 'HamStick',
I didn't think I would have to. It behaves so poorly on 40
and 80 meters that I didn't think it could be improved on, no
matter what you did with it.

Source record: 150073

JG,
The feed point impedance is lowered to something on
the order of 15-35 ohms.
Instead of saying a dipole's legs are folded back so
they are parallel, it's more 'correct' to say that the
dipole's legs are at right angles to each other. The
resulting radiation pattern tends to be in the direction
of the body of the vehicle. The pattern isn't what I
would call 'directional', as in a beam antenna, but more
of a 'lop-sided' omnidirectional pattern. This 'trend'
in direction doesn't seem all that desirable in a mobile
antenna system, but that's what you end up with when you
have to adapt to 'practical' places to mount an antenna.

Why did it cost you any money? You had to pay the driver to get the
package. That is sufficient proof that you paid. If UPS lost the payment,
that is not your fault.

I have been that route. A quick letter from my attorney set them straight.

But I avoid UPS whenever possible. They often leave packages sitting on
my front doorstep in the rain. The sometimes leave packages that require
a signature - good thing that I am honest and don't claim that it was
never delivered.

Crazy George,
I think it may depend on the type of soil in your
area. I've put down several ground rods like that and
don't seem to have any problem with the "rod not being
in intimate contact with the dirt". I can say that
when finished puting a rod down this way, there's no
chance of you ever pulling it up by hand! I'd call that
"intimate" enough...

That length of 75 ohm line is a matching section. Take a look in any
copy of the Radio Amateur's Handbook for a discussion.

It doesn't affect the efficiency of the antenna, but it certainly can
affect the percentage of your power that gets into the antenna.

Exactly, Roy!

This is represented in the classical Greek approach to what would have become science had they adopted the simple expedient of testing their theories in practice. eg. the rate at which heavy objects accelerate relative to light ones, and the number of teeth possessed by women.

I'm an academic EE BSc at heart, but have had to requalify in psychology (BA) and now sociology (BSc ... ha-ha! - "Science?")because of the UK's reluctance to employ engineers any more (or even know what engineering means). You'd be amazed at the hypotheses regarding electrical technology held by psychology and sociology PhDs!

One commonly held belief (by fellow academics) is that EE involves nothing more complex than simple arithmetic, and is a manual activity for working class students of "other" institutions. Another oddity is the assumption that there is no creative process in designing, say, a new transformer.

Returning to the topic, I knew a ham who was chucked out of uni after his 2nd year who I would employ above *any* maths PhD I have met, and many maths PhDs hold similar views to the social scientists metioned above.

As with any other qualification, the value of a ham radio licence depends on your "grades". I don't only mean the class of your licence, but what you have chosen to do with it.

For all the pessimism about things only half-learned through amateur radio, there are some young radio hams who apply for university EE courses with an extraordinary amount of existing knowledge that they could only have gained through amateur electronics. Amateur electronics has many branches today, but amateur radio is still one of the best - if you really use it.

I am completely confident about young people's ability to discard incomplete and incorrect information. The whole of science education, from elementary school to PhD and beyond, is a progression of peeling away the simple knowledge we learned earlier, and discovering the details, the numbers, and the subtleties underneath. Young people are doing this naturally and easily all the time - it's only older people who forget this is possible!

At the other end of the EE course, employers will be trying to find people who are not only qualified in engineering but also have enthusiasm for applying it. This is where a ham radio licence - used to do some serious graduate-level engineering, just for the love of it -

can really make a graduate EE stand out from the herd.

If this is your philosophy, maybe it's a good idea to learn more about the civilization and history of Greece.
When we was enjoying the civilization and learning, you was sleeping in the caves...
The word "philosophy" is taken from the Greek language like more of the words that you use, for example "psychology" , " technology" "academic", "sociology", "arithmetic", "mathematical". Does it means something for you, maybe?

Corry has a valid point. Many ECE dep'ts do not emphasize RF these days. That is not a criticism, but an observation.

Analog RF at universities is truly moribund.That DOES rate a disappointment, from me anyway.

Roy Lewallen wrote:
"I`d say that the hams I`ve known who are design engineers have, on the average, been among the better ones."

My experience is different. There were no hams who made it to graduation in my EE class. I wasn`t a ham then and I graduated.

Most of my classmates got jobs in design at major corporations, Collins, Motorols, GE, etc. They did not immediately take charge of a design group, but before long they got there, and many continued their education, getting advanced degrees.

They changed companies and jobs often. Defense was big during the "cold war" and a company winning a contract was hiring. Several of my classmates seemed to migrate like birds. Summer in Chicago with Motorola, and winter in Dallas with Collins.

I did something different. I took a high paying job overseas with no starting grunt work and stayed for a few years.

In my experience, the EE education agenda was too demanding for diversions such as ham radio.

Best regards, Richard Harrison, KB5WZI

Stefano,

> If you want
>prove your self the CFA CAN have the same efficiency of a full size vertical
>(with no traps) you can look for "stefano's cfa experiments" in the antennex
>archive.

Last years CFA tests conducted at NTL's Weston Park here in the UK had
poor results.

Comments from a friend;

The CFA passed away rather quietly during the early part of last year.
Khabbary himself seems to have slunk away with his ill gotten gains, and
apparently no longer works for the Egyptian Radio and Television
services.
Son of CFA is however alive and well, and yet another hopeful individual
is following the path....
At least this time the antenna is being submitted for FCC testing and
approval, but no-one is holding their breath....
On the subject of antennas, the biggest advantage that the Folded
Unipole has over the series fed antenna, is the fact that the bandwidth
is always greater for a given geometry.
This will always be disputed by various pundits, but is a feature of the
shorted transmission line in parallel with the radiating element.
The slope of reactance for both elements of the antenna is opposite, and
has a tendency to cancel.
This is most effective around quarter wave resonance, but is useful at
much shorter effective heights.
When the antenna is shorter than a quarter wave, there is a further
advantage to using a Folded Unipole.
Because the feed becomes inductive rather than capacitive, the losses in
the matching networks can be reduced considerably, due to the
performance of practical components.
I.e. the losses associated with practical inductors, compared to the
losses for easily obtainable vacuum capacitors.
I think you probably know that I am back with

XXXX

again, and have been
for the last eighteen months or so.
At the moment I am designing a diplexing system to enable dual use of
one of our London sites, in order to accommodate one of the new "Access"
radio stations.
It is fun to get the opportunity to combine the predictive power of the

PC with real world measurements, and see how they match up.
In the case of a Band One STL antenna, the computer model failed
miserably.....
Just shows how important accurate measurement equipment is, to confirm
predicted performance.
That's about all from here for now.

End.

Lets turn the subject around. Of the more well known Hams, which do you think (or know) have EE bakgrounds?
I know that, of the people I observe here on the net (NG and reflector), One of the ones whose opinion I respect most is an English major- One that I respect least has a Phd in Physics. Another I ALWAYS read is (apparently) an EE, with an RF base (Hard to get, these days).
Of the better operators (as indicated by being high on DXCC and contest lists), I wonder which are EE, and which are Communication majors (non RF EE).[and- yes- I know those criteria (DXCC,etc) are not necessarily good indicators].

Just curious - Bill, W4BSG (Aerospace background, not EE)

> engineering? Or is power now in the domain of ME?
>

Well, considering that I currently have a class in each, yes. :-) At least my college (voted the #1 in undergraduate engineering for three years running, according to US News and World Report) has a wide variety of both required and elective classes one can take in these fields. For example, right now I'm taking a required power systems course, which builds on the power concepts taught throughout the other classes, and goes into some detail on three-phase power, transformers, DC and AC machines, and the requisite analysis methods. Should I want more, there are several additional power electives, some involving power control systems, high-power transmission, etc. Now, regarding wireless; I'm in an elective right now which covers topics ranging from antenna gain and noise calculations to cellular sectoring methods and multiple-path propagation models to the various flavors of digital keying. These concepts also have been discussed throughout my education; I recall last year one class required us to design an FM transmitter in lab. Ours worked pretty well; essentially broadcasting a few hundred feet every whisper in a room. Should I want another wireless class, there is a wireless electronics class offered next quarter, in which various radio constructon methods are covered and 10% bonuses go to those with ham radio licenses. But I'll be taking electronic music synthesis instead...sounds like more fun and I like thinking about things in digital terms anyway (even if it really is all analog).

So I have only one quarter left...but yeah, I think there are some undergraduate programs with a decent amount of specialization opportunities. I didn't really specialize, though; I picked up most of my electives from an experimental entrepreneurial team study. Right now the team is working on the same project for senior design; a USB robotic webcam mount with integrated hub. I got stuck with programming all of the PC client software (usb interfacing, tcp/ip, video capture) and all of the firmware code (microcontroller usb implementation, motor control). Now I've only had one computer programming class; a freshman C++ course. But somehow, through hundreds of pages of documentation, all-nighters, and some luck, I'm making really good progress and already have a two-way data pipe set up over USB. Assembly code really isn't that bad :-).

That said, I'm going to graduate in May and still don't have a job. Anybody out there know of a good position? I don't take up much space! I

eat very little! I can start a fire by rubbing two sticks! I would be more than happy to send you a resume or give you a call!

Later,
---Garrett

On Saturday mornings, my ham radio club meets for breakfasts in several locations. My group usually includes 4 engineers. This morning there were only two. I told Charlie about this thread and asked his experience. It was almost the same as mine. No practicing radio amateurs in his graduating class in a different university. Charlie had a ham license when he entered the university, but completely forsook the hobby while in school because he didn`t have the time and energy for both ham radio and his engineering education.

I have a 1500' beverage that winds around in a virgin forest. I just used electric fence wire and went from tree to tree. I did not terminate it, and I don't use a transformer.

Yet....

The performance is AWESOME! Perhaps some day I will actually build a transformer, and then add another at 90 degrees to this one.

Bottom line is that the height is not too critical. Neither is keeping it in a straight line. Just get it up and see how it works!

One of the worse things you can do, I think, is make your hobby your career (unless you work for yourself and have no employees---then its fun)! What do you do when you come home after 'playing' with RF all day? I haven't turned my TS930 on for almost a month now. I am leaning now towards more low-tech hobbies.

A more direct answer, I personally know several. The most notable being W8JK. He has kept his license up, but is not active---another example of the above complaint, I guess.

And yes, I am both an EE and ham. (Notice my callsign...)

Source record: 150099

I have a G5RV between two of my towers.... the end insulator tied
off with 10-15 feet of rope to one tower and the other with 180 -190
feet to the other tower at the back of the yard. I have a "football"
field + length for my back yard. Would it help / hurt to extend
the one side of the 51' design of the G5RV with more wire ----???
Say 51' on one side and double or tripled the length of wire on the
other side to 150 feet - replacing the rope? My thought was to use
more capture area with more wire ..... Can't ask the guy that
designed the antenna - he is a "silent key".

I am about 40 ' off the ground at the center - ladder line feed -
regular G5RV... I do not want to change the center feed point as
it is coax in black plastic pipe - underground - comes out of the
ground and up between two trees.

Any Ideas?????

Thanks

Ron

Doc:
Yes, it does depend on the type of soil. To use a ridiculous extreme example, one well placed subsurface rock will make extraction difficult, and yet provide almost no soil contact. And, disturbing the soil by water jet, even though a lot of it settles back in the hole, always leaves it a lot less dense than it started, even when it is sand.

My reason for pointing out the problem is that anyone who has to ask probably also has a poor understanding of any of the principles of either RF grounding, or lightning protection, and should be aware that a ground rod installed loosely in a hole is not going to work as well as a driven one for low frequencies, nor a properly designed radial field for RF which someone else commented on. There have been measurements made of contact resistance of driven rods vs. other methods, and the driven rod always has the lowest resistance, sometimes by a lot, sometimes by a little. Unfortunately, I don't remember where that reference is, but I'll bet either NFPA or UL can come up with it, as it forms a portion of the basis for present NEC codes.

I would love to put a current probe around the ground wire of the original poster's installation, to see if it is AC or DC which is eating up his ground rods. And, more importantly, has his service entrance ground also been eroded away, so that he has no electrical system protection either? It's not likely the utility company used a solid copper ground rod.

I got my Technician and General class license last year so things may be different now then they were when you got your license. The electrical part was easiest for Technician class, had a little more for General class, but Extra class appears to have quite a bit, compared to the others anyway. I can see that an EE could easily pass the electrical parts with little trouble, but how did you memorize all the rules on which frequencies are for what and how much power you were allowed to use on the different bands? The parts that took some study time for me was memorizing the rules and procedures, and learning Morse code. If I decide to go for the Extra class license, I will have to memorize a good bit more FCC rules and operating procedures, etc, plus re-memorize electrical formulas that I learned in school and haven't used in 20 years. :-(My interests in Amateur radio came about by my wanting to put a video camera on my R/C helicopter, license is required for the higher powered transmitters.

>differential equations have to do with masses and springs?") ...

(The rest snipped.)

Mathematicians aren't supposed to know anything. In his essay "Mathematicians
and Metaphysicians" Bertrand Russell wrote,
"Thus mathematics may be defined as the subject in which we
never know
what we're talking about, nor whether what we are saying is true. People who
have been
puzzled by the beginnings of mathematics will, I hope, find comfort in this
definition,
and will probably agree that it is accurate."
I hope they weren't using a real mathematician to teach engineering math. If
they were,
you should go back to the institution you attended, Roy, and ask for your money
back.

I agree. About 20 years ago i had to staff a new satellite communications ground terminal with a few engineers. The folks I tried to hire right out of university were sadly ignorant of RF stuff. Much of what I learned in the 1950's was not even being taught any more.

In my own case, I had my extra class license as a senior in high school. During the summers I worked for Eldico Corp. at their factory on Long Island assembling production prototypes of their SSB-100 transmitters and 1 KW linear amplifiers. I built all my own transmitters for use at home.

I found the EE curiculum to be boring until I got to my senior year communications course in which I got an "A". I knew several hams in the radio club who dropped out of school because they knew they could make good money as a broadcast engineer without a degree. The hard part for me was seeing any relevance to the real world in what we were studying. Concepts of electromagnetic field theory like "curl" and design of nine-phase AC power transmission systems left me cold. I managed to graduate and had a successful 35 year career in the aerospace industry in spite of my difficulty with the content of the EE program.

That (presumably) professional engineers/scientists wasted time and somebody else's money on making tests and measurements, to demonstrate what should have been perfectly obvious to such people, is a sad reflection on present-day standards of basic engineering education in the UK.

But then, there's not much to be done with students who are unable to add and subtract, let alone multiply, by the age of 18.

1720. How Good Is the "Lattin" Dipole Antenna?

The SWR at the antenna matchbox will remain the same, regardless of what
the SWR at the rig is tuned to. Why not just run a length of random wire
for
160 meters against a ground, such as your home plumbing and then use
the tuner to achieve a good match?

If you must use the R-5, I'd be tempted to bypass the matchbox with the
coax directly feeding the R-5. The biggest problems with those antennas
seems to be toasting the matching transformer which CC will not replace
or provide engineering specifics for. Another point, the matchbox may
be extremely lossy when the antenna is used for 160 meters, or it may
provide
some matching. Who knows what the antenna impedance is at 1.8 MHz?

1723. Re: Are hams better electrical engineering students?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-26 17:02:51 UTC
From: "J. McLaughlin" <JCM@Power-Net.Net>
Message-ID: <u55o77252meb6c@corp.supernews.com>
Source record: 150111
Cross-posted to: alt.engineering.electrical,rec.radio.amateur.antenna

Dear Group:
1. Notice how many excellent people have responded to this thread - a number of observations came from people who only occasionally comment. There are issues here of interest to many.

2. Thinking back to University four+ decades ago, the most effective engineers were almost all radio amateurs. Let us not forget that being a radio amateur in those days was a lot more intellectual and practical than is now the case. Some of our best teachers were radio amateurs. Separated by years, N8EE and I both had W8JK as a mentor and exemplar.

3. In over 37 years of teaching EEs, many of the most productive engineers were radio amateurs. Mind, the best did not always have the best grades. [I remember one student (a radio amateur) who was a vigorous participant in Noon hour seminars over lunch. He flunked out of our school. Years latter, he approached me at Dayton. He had done well at another school and was then head of the part of the public service agency of a major State overseeing the electric power industry in that State.]
The Wise Roy has put his finger on the correlative factor. It is curiosity. What I have found to be linked in a ridged fashion to success (as engineers would recognize it) is a student's curiosity. That such persons should also tend to be radio amateurs (of the classical type) is of no surprise. [Mind you, some of those successful EE students now are involved with major medical research, head patent law firms, and also perform more traditional, creative engineering.] Over the years, I have seen the effects of the debasing of the amateur license in that fewer of the curious students have a license.

4. Most of the effective faculty in my department have a radio amateur license and the other effective faculty exhibit the same type of curiosity as that of the best students. Their teaching reflects broad understanding of the issues involved with analysis and synthesis. Yes, springs and mass has a lot to do with circuit analysis (and understanding).

Let us all nurture curiosity whenever an opportunity to do so arises. This group plays a positive role most of the time. 73 Mac

Hi Jerry,

Been a Butternut user here since 1991 running both the HF-6V and HF-2V. Both antennas are still in service, but have had to replace the 75 Ohm matching section on the HF-6V several times. The matching section is cut for 20 Meters as you have noted. It helps most on 20M. My Butternuts are ground mounted over 73 buried radials of from 15 to 55ft in length. You didn't mention the frequencies at which the SWR readings you reported were encountered. I don't have full band coverage on 40M either with the HF-6V, but do with the HF-2V, but have set my 2:1 bandwidth toward the CW portion of the band on the HF-6V. You should be seeing something better for 15M and may need to adjust the length of the 15M stub.

Hope that helps.

Ed, W0VC

I've run field strength tests that tend to indicate that not much radiation comes from the top of the stinger. A top hat should be kept out of the immediate fields of the loading coil. I run a 6' diameter top hat two feet above the screwdriver coil with no "stinger". This is a good way to improve clearance.

Ron, just put up the longest dipole you can manage up to a maximum of about 240 feet end to end. Length very non-critical. As high above ground as possible. If you can, feed it roughly at its centre with heavy-gauge 300, 450 or 600-ohm line. Prefer the higher line impedance. If you can't manage centre feed just do your best. Absolute centre it is not a vital necessity. Whatever you do, practically all the power you put into the feedline will be radiated in some direction or another.

It doesn't matter if, in order to feed nearer to the dipole centre, the feedline comes away from the antenna at an angle considerably different from the ideal 90 degrees.

If you have any coax in the feeder consign it to the junk box. Bring the feedline right into the shack if you can manage it. Fit a choke balun between feedline and tuner. There may be any length of coax between tuner and transmitter but the shorter the better of course. It's convenient for tuning-up purposes if the SWR meter is at the tuner end of this coax to the transmitter.

You will then have the most efficient, all-band 160 to 10m antenna possible at your QTH.

Taking one band with another the antenna can be considered omni-directional

If you are numerically inclined you may find program DIPOLE2 of interest. Models any centre-fed dipole with any type of feedline plus L-match network component values. Download in a few seconds from website below and run immediately.

1728. Balun question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-26 18:07:48 UTC
From: John Mortlock <jmort@global.freeserve.co.uk>
Message-ID: <a2ur52$t1s$1@news7.svr.pol.co.uk>
Source record: 150115

I just purchased a used 16 ele NBS 2m yagi from a nearby ham.

The driven element is a folded dipole.
I noticed that the length of the coax cable used to form the coaxial
balun has a total length of 26".

The usual 4:1 coaxial balun is 1/2 wave long or about 41" for 144.300 MHz.

Can anyone suggest a reason as to why the coaxial balun is 26" on the used
2m yagi I just bought ?

Different impedance transformation ratio maybe or just downright wrong ??

Thanks,

1729. Re: MOBILE helical help...?

That pretty well duplicates my experiments as well - which at least helps keep larger capacity hats
outta the trees and overhead wires - and here's still ANOTHER variation... After a small "incident"
with a tree, I found that when the same circular array capacity hat had all the "spikes" rearranged
to the REAR area of the vertical whip, it still loaded the same as it did when they were arranged
radially around the whip - it seems the physical area/number of hat radials is more critical than
actual layout (only to a degree, I'm sure!), at least in terms of system loading. Sure would be
interesting to see accurate, in-depth test data on the subject!

Look into a Windom antenna... If memory serves me there are too
different lengths to the radiators that would probabily fit the bill for
you.

Hi All,

Like Roy, my EE grades were barely enough to escape the draft, but not good enough to motivate me to stay away from it. I soon found myself in Uncle Sam's canoe club in '68 (the lottery was still years ahead, and a 2.0 was the draft breakpoint).

Hardly mattered.

When I emerged to return to academia, I was well educated (courtesy of the navy of course) and a skilled educator in Electronics. I re-entered the EE program, but only for months when I found that the instructors were pathetically trained for instruction, poorly motivated, and they had labs full of instrumentation I could not only fix, but calibrate, and explain the intracies of theory that enabled their operation - all sitting dusty on upper shelves with no apparent use. The last straw was my phD standing before me READING verbatim from the same text I toted to class every day - such a poverty had me out of that morgue quickly.

This is not to denigrate colleges and their engineering schools, I was highly motivated by one particular Dr. Richard Blade (University of Colorado, Cragmor) in three semesters of Physics. The one overriding concept he taught was that numbers add up to nothing (to quote Neil Young) - sorry Punchinello, monkeys can scribble numbers and still have to go home to their trees for all their effort. Of the 100% available for scoring any test, the answer only accounted for 5% and we were allowed to be within one order of magnitude. What we were graded on was how we got the answer. This simple principle quickly separated the wheat from the chaff. The fixation on numbers to the exclusion of thinking was anathema.

So. You go to school to learn, not to find a job. I've been saddled with too many engineers who saw only a salary, not a diploma when they studied. On the other hand I've trained innumerable techs that eclipsed these sad souls who eventually worked for them!

When I walked away from the shocked EE program toward the even more shocked English counselor it was toward an ethic that encouraged analysis and thinking over the soul hardening paralysis of scribbling numbers. That same counselor offered in honest self appraisal that

there were few jobs waiting for English graduates. I responded I had a job, and had been working in that field for nearly 10 years. I later capped that with another degree in Cinema (BA squared if you will).

This is not to say I have an antipathy for numbers. Most here will recognize my web published work is replete with them. Further, my career in Metrology can hardly escape their application out 6-12 places. However, such numbers were a consequence of a method, not a goal. Without the fundamentals, those same 6-12 places could have as easily consumed 5-11 places of numerical noise.

As I pointed out to Jason earlier, if you do not have the experience and talent of a tech, as an engineer you are little better than his tool caddy. If you do not have the motivation to seek out that same experience - you are dead in this economy.

Not an engineering graduate, I have nonetheless done work that most engineers would kill for, but they were on the MBA fast track watching from the sidelines. My design work has included Avionics (sole designer of the black box HW/SW for the 757/767) Medical Electronics (blood-gas chromatographs), Instrumentation (fiber optic based oxygen sensors), Basic Research (contributing editor and researcher to 5 NIH Grants), Optical storage (4 patents), Process Control (1 patent), RF Instrumentation (Spread Spectrum, albeit in the software side of the house), and some several many years of Internet programming (with three dead dot.coms behind me - managed by those surviving MBA's, the exposed corrupt tip of the ENRON/Anderson iceberg).

I just installed a used HF6V and had to replace the 75 ohm linear transformer. I used the formula in the Handbook to calculate the correct length and then an MFJ 259, with an appropriate adaptor, to actually cut it to the correct length. Using the correct coax cable velocity factor and cutting per the formula will work just fine.

Check out their Web site for a lot of interesting information on verticals, including the need for radials.

>
> Any comment?

If you can move it up and down, and see little difference in the
number of coil turns needed, then it's not making much difference as
to it's position. Top hats on mobiles I have never used. Mainly
because my antennas are all light weight, and a hat would add too much
wind drag. As far as X type hats with no connection of the spokes at
the ends, I think they are a waste of time overall, unless you just
have to have every single drop of performance. I think a solid plate,
or an X with connected ends works better. Myself, I avoid all the
hassle of hats, and just use the longest whip I can get away with.
Decreasing a couple of three turns of Hi-Q coil, from use of a small
hat really isn't going to make much of a noticable difference in the
real world. Or I don't think anyway. Now if you can use a BIG hat ,
and lose 1/3 of your windings, now you are getting somewhere. :) MK

>http://www.qsl.net/sv3eao
>

Hi Fotis

The point I was making is that many hypotheses held by famous classical Greek philosophers are simply wrong theories about the physical universe - the two examples I gave are just that, simply examples.

Others might include:
1. "All movement is an illusion as since vacuum doesn't exist, movement is impossible."
2. "Each new day is actually lit by a different, entirely new sun."
3. "There are four elements."

Naturally I have the greatest respect for modern Greek engineers, technologists and scientists, all of whom test their hypotheses against reality. However, many famous figures from classical Greek history did not.

The link with radio amateurs is that if, as a ham, one builds an RF amplifier and it doesn't work, one will not be able to claim that it does work as this statement will so obviously be false. A theoretician, who states in public that experimentation is beneath him (or perhaps ignores its results) however, may inadvertantly create an entire literature of "knowledge" which is false.

Naturally, we owe a great debt to the Greek language with very many English words, but although their etymology is from the Greek, the modern meanings

of the words psychology and sociology do not have a significant link with classical Greek civilisation. Classical mathematics was of course entirely pre-calculus (not to mention pre-zero!) and a great deal of arithmetic is Arabic in origin.

Finally, regarding my ancestors, my [Great]^112 Grandfather is well known for having been the chief design engineer working on the Stonehenge analogue astronomical computer project ;-)

Best wishes

Nick Sheldon

I had this very samething happen. They put the wrong label on my package and my label on another package thus, the two packages were sent to the wrong parties. I contacted UPS and they took care of it for me. Not willingly at first because they couldn't believe that could happen. They contacted both parties and explain their mistake, picked up the packages, and made it right.

WELL, if you're already "pushing the envelope" of available height in the mobile antenna system, and
modeling programs show a fairly significant gain to be had with a couple more feet in the whip, the
added effective impact of the top hat IS worth going after - AND, if that benefit IS obtainable even
with the hat slid down significantly on the whip, it's almost like getting something-for-nothing...

I agree, and my own testing proves (to ME!). that about 6 top hat radials, tied circularly together
at the ends and mid-point provide a very effective capacity element - and as is the case with many
HF antennas, the benefits just keep increasing as size does... It's just a matter of how much you
can physically install on a vehicle that actually must be driven, and how much ugliness you can
tolerate! :-)

They were, and the money spent for the course was wasted. But that was only one of many courses in that category. I did learn differential equations, finally, in a course in linear control systems, taught by one of the few capable engineering professors I had.

I have to say, though, that I definitely did learn something in those years of EE schooling. Over my career, I noticed something very interesting. With rare exceptions, there's a striking difference between how a graduate engineer and one without the formal education approach a problem. The person with the formal education takes an analytical approach, while the person lacking the education takes a more emperical approach. The latter can be used to solve some problems, but isn't nearly as powerful as the first, and is inadequate and fails in many cases, particularly when dealing with design problems. I'm not certain how this comes about -- I guess just seeing so many problems being solved by brute force analysis, plus the knowledge that we can dig out an analytical answer, with books or whatever, gives the confidence to look at problems the way we do. Only a very small fraction of working design engineers could solve even freshman integral calculus problems, let alone a differential equation, a few years after graduating, but then very few ever have to. But it's nearly always possible to spot whether someone has undergone the formal education just by the way they approach a problem. I've often wondered if an EE education could be made tremendously more efficient and effective if the schools only knew what the students were really learning. (More likely, they would screw that up, too, so it's probably better to let it lie.) Education, it's said, is what you have after you forget everything you've learned. I maintain that the education gives us this approach to solving problems, and some basic tools to do it with.

Of course, I've also known some striking exceptions to this generalization. I know a number of excellent engineers who solve problems with an analytical approach but who haven't had a formal EE education. But they make up no more than a couple of percent of the engineers I know. So I'm convinced that there is something we learn in grinding through that process. Whatever it is, though, it doesn't seem

to have much to do with GPA.

You have a good point here. As a former military flight instructor some
of my most problematic students were those who had private pilot
licenses. I knew a guy with a commercial ticket who flunked out of Navy
flight school - couldn't teach the old dog new tricks.

Most of Tektronix's products are time-domain oriented rather than classical RF, but for many years Tek had a line of spectrum analyzers as good as any in the world. Spectrum analyzer design requires some of the most demanding RF engineering talent, and the spectrum analyzer group at Tektronix had some truly world-class RF engineers. Many of them were hams. (One of the better known is Wes Hayward, W7ZOI, who was in that group for years but left some years back to finish his career at TriQuint.) All those I knew in that group who were hams had gotten their licenses as kids, and gone on to make a career out of electronics, as I had. All the engineers in that group had EE degrees, some BS and some MS, except one who had a physics degree and one with a BS in physics and a masters in EE. Incidentally, one of the very best electronics design engineers I know has a BS in physics and no engineering degree. He's also a ham that started as a kid.

>. . .

I did an analysis of this effect some time ago in quarter wave folded monopoles, and found that although the stub reactance change is in the opposite direction to the antenna reactance change, the contribution of the stub's reactance is so small that it's virtually negligible. The transmission lines making up the stubs would have to have a characteristic impedance of only a few ohms in order to have an appreciable effect on the bandwidth. The bandwidth increase seen in a folded monopole is nearly entirely due to the larger effective diameter of the radiating structure, and you can get very nearly as much increase simply by paralleling the same two conductors and feeding it as an unfolded monopole.

I'm not sure of the makeup of your balun, but you don't want a 4:1
impedance transformation. In a Yagi, mutual coupling lowers the
feedpoint impedance of the driven element. The driven element is folded
to get the impedance back up, probably to the vicinity of 50 or 75 ohms.
Whatever the feedpoint impedance, it's almost certainly well below 200
or 300 ohms.

If the SWR is good, the impedance transformation is correct.

I guess what I meant was that the radiator is running vertically parallel to
the vehicle body up to the point where it clears the top of the car
.
So the radiator ends up parallel to and close to the "ground plane" for some
distance.

If it is a bumper mounted 8' whip, say, on the back of a van, this parallel
condition is present along most of the antenna!

I hope this might clarify my question...

thanks

The makeup of the balun is:

Inner of feeder coax to one side of folded dipole and also to the inner of balun loop coax.
Inner of the other end of the balun loop coax to the other side of the folded dipole.
Outer of feeder coax and outer of both ends of balun loop coax joined together.

The balun loop coax is 26" long.

Thats why I think unconnected hats are a bit of a waste compared to ease of use vs performance gains. If you had the hat at the top with unconnected ends, you can have 8 spokes 2 ft long, or 2 spokes 2 ft long , and the performance is not going to be much different either way I don't think. The total length added is still going to be about 2 ft either way electrically. Myself, for the light antennas I use, I'd prefer to just add the 2 ft as a taller stinger with no hat. It does about the same thing with less clutter. I use long thin stingers that just flop across anything they hit. Now, I would think an 8 spoke 2 ft hat with connected ends would outdo the two 2 ft spokes by a decent amount. But I'm not sure how much without looking into it farther. I think if I ever added a hat, which I may do for 160m, it will use a solid plate , or spokes with connected ends. You don't really get your moneys worth otherwise I don't think. MK

That all depends upon which University you are talking about. There are
still a few who do...

but the "mainline" campuses are far too enamored with the "hot topics",
which can generate high salaries for their graduates, i.e. Internet
protocols, ATM, VLSI design, etc...

In the old "radio days" we never studied Morse Code at University, why do we
study tcp/ip, atm and frame relay, at University today?

Cuz it pays the big bucks.

Frankly, I got my Ham License (30 yrs ago), a few months before my
1st phone, just to test the waters for FCC licenses. Both were quite
easy, but I was 15yrs old, and things seem to be easier when one
is both interested and young :-).

When in college (EE), I found that true technical knowledge actually does
help (for context issues), but there is alot of technologist malarkey
that isn't real 'knowledge'. One of the most important maxims no matter
where one is: don't think that you know more than you really do.

I aced practically all of my EE classes (easily.) However, I had a good concept of
what I didn't know, so was happy to learn new things (not trying to be
Joe Stud about all things EE.) Later on in my school career, one of my
profs ended upon working on my projects for me in industry. In his classes,
my grades became more difficult to get, so as to avoid conflict of interest.
He is one person who is my senior, who I still have great respect for, and
hope to contact him someday again.

It is pretty clear that there is some value in having previous experience, but
perhaps some pseudo-old-pros (without adequate deep theoretical
knowledge) should recognize that practical experience (and alot of ad-hoc
know-how) aren't everything that make up a successful and functional
EE. There have been some allusions to Physics people being good EE's,
and I have also found that those Physics people who choose to be good
EE's are often VERY VERY successful.

I agree. I've been shipping my Ebay packages exclusively with Fed-Ex Ground and haven't had a single problem. They are faster, cheaper, and friendlier than UPS will ever be. I haven't had them once ask about how an item was packaged or opened a package at the counter to find out. Fed-Ex Ground will usually beat their "estimated delivery date" by a day or two and they've been known to deliver packages on Saturdays and Sundays at no extra charge.

I'm in Puerto Rico and Fedex treats this part of the US like rural
Zambia or something. By their definition, PR is an "international"
destination. A recent ebay purchaser pointed out to me that he could
ship a 15 pound printer from Indianapolis to Miami, dropoff/Fedex ground
for $7 and change. Same item to me costs $40+. And if I'm the sender I
get stuck with pickup charges (no local dropoff point) and we don't have
Ground Service anyway. (They don't publish the tariffs on the local
website but my last ENVELOPE sent was $27)
As much as I despise that sort of overtly discriminatory business
practice, I'd sure like to have the same service available so that I
could thumb my nose at the ever-increasing USPS Priority rates....even
tho I can't complain about their service.

Hi,
It's time to do an antenna upgrade, and I need a recommendation.
Right now I use a Icom t7H HT (2m/440 Mhz) as my main rig. I have the
stock antenna, and a roll up j-pole for emergency use - I've joined
ARES and want to do an equipment upgrade

I'm looking for 2 or 3 antennas

1)a good Gain antenna (prefer flexible) for portable use
2)a good Magnetic mount antenna
3)a Base antenna

Help

Pete........the Lattin has been discussed here more than once. As far as I know, no one in this group has been successful in building a Lattin. I tried, several times....used up a lot of wire, but had confusing results......non-satisfactory results.

You might try searching this group using keyword "lattin" ......
You will get several "hits", and those hits, if read, will more or less summarize the efforts and interest of this group in the Lattin antenna.

I still wonder......if a knowledgeable person, using a combination of antenna modelling.....and one of those "Antenna Analyzers"......might that person successfully build a Lattin? I would sure like to see that happen. I have been intrigued by the Lattin antenna for a REAL long time.

Agreed! His main accomplishment was turning the theoretical work of others into a commercially successful communications system.

Major Edwin H. Armstrong, on the other hand, was the genuine engineering article.

Would Philo T. Farnsworth be considered an "RF engineer"? How about Jim Lamb?

Thinking about using a rohn h40 or 50 mast for a mosley ta-33
jr.......leaning more to the h40....need to have abt 35 feet.to clear the
peak....have a alliance hd-73 for the rotor ....attach rotor to mast and use
maybe a 5 foot mast for the beam.....the mast would be secured at the base
of course and will be secured at the house at about the 20 foot mark(2-story
house)....then could be guyed above that by 3 points......Do you think this
would work and if anyone has...did you have any problems...since i have
never used a telescoping mast ...how strong are they extended.....and can
they be raised to the verticle once extended...if anyone has ever done this
would be interested in your expierences

That is probably an apt analogy. Both men had a genius instinct for knowing what was practical. Both were hands-on operators.

Ford was an automotive innovator before becoming a mass manufacturer. He hand-built his first racing engine on his wife`s kitchen table.

When Ford took his race cars to the track, people thought FORD was an acronym for First On Race Day.

It will work fine until the wind blows. We've done this on field day for
years. Fortunately, the wind has held off so far.

> did you have any problems...since i have
> never used a telescoping mast ...how strong are they extended.....

Not very. Heavy guys at each joint would still be marginal with a 3 element
beam on top, especially with the 5 foot lever arm above the rotator.

> and can
> they be raised to the verticle once extended...

Not easily. You need to lift each section to keep it from bending.

Ahh, this is true..... The simpler of the two would be an off center fed dipole.

A book I have in my collection by G4LQI, Erwin David, also shows a "Windom" (by I7SWX, Gain Moda) using a 4:1 transformer at the feed point with 75 ohm coax feeder that looks like a new spin on the OCFD. The ARRL antenna bible shows the classic Windom configuration only.

I had been reading the book last week, that's why it popped into my head

You guys need to add somthing flashy to serve as an antenna. Add one of those elevators race cars use to give high-speed traction to the rear wheels, and insulate its attachment to the car (truck) body. Make it from metal and it`s your capacitive antenna hat. A wire down from the center is your inobtrusive antenna.

Did he have a separate kitchen table apart from his wife? These days
one might have to say "wife's kitchen table" but I would like to think
Mr. Ford in that era had the cojones to claim the table as his own, or
at a minimum, "the kitchen table".
When friviolities like that are added to a statement, it makes one doubt
the whole story.

Don't get excited, I'm just nit-picking.

I had a friend, recently a Silent Key, VE6TD (Bob), used a
Lattin for 75 thru 10 meters and seemed to have success. I
have one cut in my basement waiting for spring -- as soon as
I string it up and run my MFJ-259B on it, I'll try to
remember to let this group know. I see no reason why it
shouldn't work -- the princples are well known.

I have the R-7000 and the major problem is the aluminum wire coming out of the traps getting corroded or loose or both. Using a slightly larger screw and a star/lock washer and penetrox has taken care of the problem. Also mount the R-7000 right at the top of the base mounting mast (fence post for me), if lower it screws up the pattern. I use a coaxial choke in the feedline and this helped keep RF off of it. I run a kilowatt to it -- as long as you stay in the R-7000 bandwidth - no problems here. Others that I know have used an external tuner and hi power and have blown the traps.

Works well for a vertical on all bands but 40M -- suspect its rather inefficient there and the band width is grim, otherwise happy with it in the other bands.

Maybe save u from buying a new one.

I will never use them and I'll bet most of the people standing up for them either work there or own stock in the company! There is no way they can give proper care to your parcels as they hire college kids and most of the handlers are replaced every semester, I worked there and they had no training, no breaks, and you were told to run to the time clock when they got to the point they could spare you for the night.

I had a person ship an item to me ups and it arrived with a split in it, from a drop of at least 10 feet. They acted decent on the phone, but gave me the royal run around. They give you a step by step process that just goes on and on until most people give up. They wanted to have a driver pick the item up and then give it a ride back to the original shipper and have him deal with the damage----but I had already paid the individual for it, and he had little motivation to collect for me! I was told by ups that I had no rights to make a claim, as if I had no idea what the item was worth, although I had just paid for it!

At first they said that if the claim amount was less than $100, they could just pay me and let me keep the item. When I took the package up to the ups customer service office here, the girl started telling me she could not do what she had said earlier on the phone and again started to try to just send it back to the sender. I asked for her supervisor. Now I got the full UPS BS--it was probably shipped pre-damaged, it was re-used packaging, it was improperly packaged, etc. The fact you have insurance means nothing, they can still use all their delay tactics on you until you give up. They would only send it back to the shipper, and he had to spend a lot of time going around and around with them to get the claim paid a long time later.

The sick thing about this is that people use UPS authorized service centers that are conveniently nearby, and most people think it is the same rate everywhere just like the post office! In reality the Mailbox etc. and all of them charge whatever they want---and most people never question it. For what you are paying you could be paying less for FedEx overnight! The last time I went to Mailbox Etc. they wanted $36, I asked how much of that was their upcharge and they said, we don't know, it is figured in the computer! I drove it over to the real UPS shipping office and it was only $18!

1797. Re: Mast Issues

Newsgroup: rec.radio.amateur.antenna

I think a Google search will bring up discussions about this from
a year or so back. If RF being coupled to the mast is an issue,
which would affect the take-off angle, you would also have to
include a choke balun at the bottom of the antenna if you go to
an insulated mast. after all, if the RF
will couple to the mast it will also be an issue on the coax feed's
outside shield.

Who the f*ck are you calling an idiot, you dickhead. I'm not so much of an idiot that I sailed through the RAE without a struggle. I *did* the legwork, you cheeky F*ckwit, by having a passion for electronics, building cicuits since I was in primary school and working in the trade, without schematics, for several years. Who the hell are you to judge me? If you didn't sit the RAE for fun, then why the hell *did* you sit it? Read the title *Radio Amateur Examination*. It's for hobbyists who want to participate in the *hobby* of Ham Radio, not just for professional gain as a certificate to wave in an employers face. I went into the exam to see if I could pass, simple, and gave it a year before I decided to jack it in. If I don't meet your criteria for sitting the exam then tough sh1t, the examiners didn't seem to mind. I guess all the other people who sat it for fun are idiots too, just don't mention that at the next RSGB meeting, you pr1ck. I knew the theory before I sat the exam, and had close friends who are radio amateurs. I guess that makes me an idiot

Nope, that's not true. Every spoke that is added reduces the number
of turns required on the loading coil.

Pete,
A couple of years ago I tried something simular to the
'Lattin' antenna. After a few days of 'fooling' with it,
I decided it was one of my more spectaular failures. I
couldn't get it to resonate anywhere except 80 meters, the
'stubs/traps' seemed to have no affect at all other than
to add weight to the antenna.
I didn't know the thing had a name, or that it had been
tried before. Think I'll go look for that thread...

Yeah OK I was *really* angry when I wrote that, but I responded to an
insult, I didn't start anything. I guess I don't like people insulting me in
public and I blew a fuse, but I guess I'm not the first and I won't be the
last. Have you never lost it? I guess you are a special breed. The whole
point is that Jim Weir seems to think those of us who served our time and
been hobbyists all our lives aren't worth as much as someone with a piece of
paper, and he insulted all radio amateurs who do it for fun, rather than
personal gain. Despite what he wrote, I studied for my RAE, but by teaching
myself electronics from a very early age, rather going to college, and I
```

felt he directed a slur at me and others like me. He implied I did nothing to earn my passes, and that was unacceptable to me. I made it perfectly clear in my post that I was a long-time hobbyist and professional, a point Mr Weir seems to have ignored. I did find the RAE easy, so what? Mr Weir seems to resent that, but I must have learned is somehow, you can't guess your way to a distinction.

I'd like to add 30 meters to my hustler vertical. What does the 30-MTK consist of? What's involved in installing it? Is the antenna harder to tune for the other bands with it?

I can't get a photo of it--I presume it's a trap and a pipe--from the Huster website or any on-line catalog.

They do pretty well if you connect the ends. If I were to add a hat on mine, it would have to be about 2 ft above the coil. Being mine is so flexible, I'm afraid if I put a hat on it, the wind will really cause it to flop around. Also I'd be likely to whack it on trees quite often. So I take the loss of not using one. But I may need one on 160 to get decent results. I haven't had any trouble on 80m without one. Using a bugcatcher at 40m with 6 ft mast, 3 inch coil, 5 ft stinger and 4 ohms ground loss will give about 56% efficiency using about 33 turns of 3 inch coil. Adding enough hat to electrically add 2 more ft to the stinger would raise to 62% and you would need about 29 turns of coil. It's an increase, but not huge. But being as you want to get every last drop, you want to use one. I'd also pay real close attention to the grounding. That will make more of a difference in performance. I have a car and a truck. You would think the truck would be better, but the car is so far. The reason is on the car, I have the antenna mounted on a hole mount on the trunk with lots of metal under it. On the truck, I have it mounted on the front of the bed behind the back window. It doesn't have much metal under the base in comparison. I could tell the difference on 80m, right off the bat. I think I'm

going to move the antenna to a better place on the truck, or put a metal plate under it. I've already done the bonding drill with strap and all that. It might have helped a bit, but I think my car is still the better platform due to the trunk mount. I've found metal under the antenna seems to make quite a difference on the low bands. MK

I've tried a few weird things but found you don't want any part of the antenna close to the car body. I once tried wires running from the antenna up to the front of the car, and tied off with insulators as a long hat. It worked terrible. It only works if you lead it away from the car to be tied off say to a tree. I'm not sure what you mean by elevators. Traction bars maybe?? MK

> Wouldn't this pose problems?

It's not desirable. They do it probably because they have no other
choice. it does effect the antenna. If the car body is next to the
coil or stinger above the coil, it will kill the antenna deader than a
doornail. The SWR will look ok, and it will act like it's working, but
it won't radiate worth beans. Having the lower part below the coil
against metal has a less drastic effect, but it's still not really
good. MK

Roy:

About Marconi... Agreed!

But how do you explain the Nobel Prize awarded to Marconi? Nothing against Marconi, but I always wondered what justified that particular award.

I believe that in years past there were a great many more professionals in our hobby than today. Incidently I have a copy here in my personal library of a facinating old hardcover radio book/manual...

Elmer E. Bucher, "The Wireless Experimenters Manual", Wireless Press, Inc., 1920 New York. p.360

It is quite scientific contains a lot of early 20th century radio engineering oriented material in its' presentation and content. This copy is in pretty good shape as well. The forward is dated May 1919.

In the back of this wonderful book is a one page advertisement and a solicitation from one...

Gugliemo Marconi
President - National Amateur Wireless Association
326 Broadway, Room 303, New York, New York.

I quote... "President Marconi...extends a cordial invitation to all amateurs and clubs to affiliate with a forward moving organization of amateurs..."

Was Marconi a professional or an amateur? Was he an EE? Clearly he regarded himself as an amateur in this context.

I suppose the NAWA was an early competitor for the ARRL, but jeesh... with a Nobel Prize winner as President... what were the ARRL founders up against? Maxim and Tekla were great, but couldn't really hold a candle to Marconi and his prestige.

Here's the names of of the National Advisory Board of Vice Presidents of the NAWA listed below President Marconi's name, all hams...

Prof. Arthur E. Kennelly, Harvard
-Co-discoverer, with Oliver Heaviside, of the ionosphere!
Prof. Alfred N. Goldsmith, College of the City of New
-A founder of the IRE, predecessor of IEEE, and first editor of Proc. IRE.
Rear Admiral W. H. G. Bullard, USN Director of Naval Communications -Need I say more...
Major General Go. O. Squier, Chief Signal Officer US

-Ditto...
Prof Charles R. Cross,
-One of the early great's in EE at MIT.
Elmer E. Bucher, Instructing
-Author and ham who calls himself an Engineer and was one as well.

Notice that Elmer capitalizes the word Engineer, he does not use lower case engineer!

Other interesting stuff: In the application for NAWA membership is a questionaire that requires the applicant to give two good character references along with their addresses! They also want to know the applicants age and call sign, and inquire if the applicant holds a government licence or proposes to apply for one! Apparently it was voluntary and not required. Incidently the yearly dues for membership in the NAWA were $2.50!

So... tell me... DID EE majors make good hams in the "old days"?

Best,

--Peter K1PO

Hello Garrett,

Good luck in your job hunting, things are tough for young graduates
these days. My disciple was trained initially before he started his EE
course in my workshop in practical skills during his vacation he
worked as a tech for his current employer(SMART MOVE) when he
graduated they knew him and gave him a job from which he has never
looked back.

Capacitance is not, as might be expected, proportional to hat area.

For N greater than 3 or 4, top hat capacitance of a set of N radials is
approximately proportional to diameter and to Log(N).

Program TOPHAT1 says that a circle of wire around a set of radials is worth
another 3 radials.

So 2 radial plus a circle = 5 radials, which is very worth while.

120 radials plus a circle = 123 radials, which, electrically, is clearly not
worth the time and trouble of another 120 soldered joints. The circle,
however, does make a much more stable mechanical structure. It also
reduces the risk of having an eye poked out.

I Think what your experienceing is signal overload of your TV. this is a
tuff one to beat.. Suspect your getting into the preamp in the Sat dish.
Try placing those Ferrite chokes on the incoming Sat. Dish feedline.. also
on the power cord of your rig.. ,The Radio Shack snap ons are ok but you
need more that just a few usually about 10 to fifteen of them to make a real
difference but use what you have and see if it make any difference.

Also forgot to mention.. the strap connected to the Hot water line may not provide any Rf Grounding at all. Most domestic water lines are brought into the house with plastic pipe these days and provide very poor grounding potential if any at all. Just because they used copper in the apartment does not mean they did coming in to the house.

1822. Re: Do EE majors make better Hams?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-27 12:43:11 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C53F5DF.27EA297A@eznec.com>
Source record: 150009

I see that I sold Marconi short. A web bio of him indicates that he was quite an experimenter, and got a patent for "the world's first wireless telegraph" and several others. He also did considerable experimenting with propagation, and was awarded numerous honorary doctorate degrees. The Nobel prize was for physics. A short biography that should be credible can be found at http://www.nobel.se/physics/laureates/1909/marconi-bio.html. It looks like he could justifiably be considered to be an EE as well as a physicist. My apology for minimizing his contributions.

The balun must take into account the velocity factor of the coax. solid poly
is around 0.66 and this equates with your length.
It is not unusal for V/U yagis to use a balanced Tee match- where the feed
then is 200 Ohms balanced and the 4:1 brings this back to 50 Ohms. Every 2M
EME yagi I have seen uses this technique.

When I was at Ohio State in the middle of my Master of Science elec. eng. curriculum Professor Curt Levis (a real character) asked, in the middle of a propagation class, if anyone was a ham. At the time I was not and can't remember if anyone raised their hand.

That was the only time in 5 years there (Bachelors and Masters) that the question ever came up.

It's likely the Yaesu FT1000 big 200W transceiver. I have the manual in English for mine. In English it is a pretty good sized book!

>So I'm convinced that there is something we learn in grinding through that process. Whatever it is, though, it doesn't seem
to have much to do with GPA.>

Could the real value acquired from graduate training be the ability to start at the beginning of any problem and doggedly step through it--piece by piece--without being especially focused on the outcome?
Only when one is unclear about the process does the outcome loom ominously large.

> Don't you mean 'coffin nail' ?

Excuse the OT:

Re. "deader than a door nail"

The early settlers in North America used to burn down their unwanted structures with the intent of fishing through the ashes to retrieve the valuable nails. Wood was (obviously) readily available, whereas nails had to be brought from Europe.

Apparently, the "door nails" were installed in a manner (bent?) that rendered them useless and so they could only be used once.

Thus the expression.

When I was a kid I would ride over to Joe Reisert's house on my bicycle. He was a year older than me. I drooled as I saw his breadboard 813 amplifier with the purple glow blinking as he keyed his rig. The fact that we were just inches from thousands of unguarded volts did not phase us. After all we were kids and invincible. As W2HQL and a 6 land call I don't remember and later W1JR, Joe was a regular columnist for Ham Radio magazine. When I last exchanged e-mails with Joe, a couple years ago he had swung from being an RF design engineer to running his own company making antennas for the wireless telephone industry. While he was collecting nearly every DX and VHF/UHF award available in ham radio, he managed a very successful career in RF engineering. But he did it with a EE degree, You needed the paper to get you in the door, Once you were there, nobody cared as long as you produced.

We know shorting out turns on a bugcatcher coil lowers
the Q thus increasing losses. If the installation of a
top hat requires shorting out turns on the coil, it
won't do as much good as it will with an unshorted
bugcatcher coil.

That's the key. Hobbies = interest.

All other things being equal, someone who is interested in
something will most likely do better at it than someone who
is not.

But the fact that someone has a ham license, these days, is
not nearly the indicator of EE related interest that it was in
the past. Sad, but true, many hams are nothing more than
appliance operators. I have talked with many on the air and
in person whose knowledge of electronics is less than stellar.
I'm talking about licensed hams who do not even know Ohm's
law.

That in no way diminishes some of the exemplary achievements
of numerous hams - but it does indicate that, taken by itself, a
ham license is not an indicator of technical/scientific interest or
accomplishment. Some people just like to talk on the air. To
them, electronics is not the "magic" that it is to those of us who
are truly interested.

> it. On the truck, I have it mounted on the front of the bed behind the
> back window. It doesn't have much metal under the base in comparison.

HMMMmm - interesting - I have much the same configuration, tho' MY antenna mount is a bit
further
back, even with the front edge/corner of my tool/fuel box in the bed of my truck - all well
grounded
with broad strapping to both the box and bed of the truck, as well as a couple of 25 foot
or so
lengths of additional strapping braid run around and across the bed area of the truck.
Perhaps a
well grounded metal bed cover would provide better ground-plane, but wonder if the hassle
would

really provide enough additional performance to justify the effort over and above what I already
have?

Hi Rick,

Going from undergrad directly to graduate school is no more useful
than getting a ticket punched as a resume line item. What you
describe as the ability to start at the beginning to continue to the
conclusion just doesn't often happen in real life and as such
represents both an illusion and the maintenance of an haphazard
approach to "education." That is, it is a grazing mentality of
specialization when no basis in experience has led one there. This
works fine for schools-as-business, but does little for the student
except take their money and occupy their time with scrambling for T/A
positions (which is their principle form of learning).

It is only by virtue of this side-effect of becoming part of the
dialog of education does anyone truly learn, and being responsible for
the right answer motivates the "instructor" for greater achievement
than the sophistries of writing up a study and columnating numbers
(all of which goes immediately into the academic obituaries, DOA).
This comes of my experience of facing a class room of 25 - 30 tech
students 40 hours a week for 3 years, many of these students from all
over the globe. Every one of them was sharp as a tack and just
looking for a crack in a technical issue to open up with the wedge of
a devastating question. I would point out that both sides of the
podium was motivated to perform, lest they found early service aboard
a destroyer as a snipe in the Gulf of Tonkin. One of the Chiefs I
worked for had a direct line to BuPers and could have a kid's orders
cut in four hours (the C-average acid test from another perspective).

The only greater motivation to learning is to break something
important. I've had plenty of experience, early on, of that too ;-)
...and I still enjoy getting into trouble.

Hi OM,

Actually the expression door nail was drawn from the hasp closure for
the door and the nail was the wedge in staple of the hasp.

The "dead" in that expression is used in the same sense as "fast"
means tied securely. Consider the implication of "dead-bolt" (which
the etymology would suggest is another, seeming, contradiction).

Language is no more easier than RF to understand at times, and the two
combined bring the lifeblood to the newsgroups.

I have a B&W low pass filter for HF.

No, I'm not interested in tinkering with it. I'm just trying to analyze it while I review my electrical engineering theory.

I'm trying to figure out the value of the capacitors, and the dielectric constant is the one thing I don't know. I can see that there is a thin material that seems to be plastic used between the round metal plates and the chassis.

Does anyone here know what this material is (or might be) and what the dielectric constant of it is?

Hello,
What is the best antenna for HF.
A)Hustler
B)Comet
C)Alpha Delta
D)Hamstick
E)Other please specify.
What I am Looking for is best performance on 10 thru 80
whether they have to be put up each time I change bands
or what they dont have to be Multiband.ButI want best performance
and or bandwidth.Thanks Mike

Good evening, Reg.

Any particular reason for the choke balun, if you have a tuner that
takes balanced feeders?

I have a 160-meter inverted V, up 60 feet at the center, and fed with
450-ohm line that connects directly into the back of a Nye Viking
tuner. It works beautifully on all bands 160-10 as well as MARS
frequencies outside the ham bands.

No self-respecting ham (sorry Roy <g>) should use UPS. They are behind an effort to encroach on one of our ham bands on a "non-interference" basis. Of course this will be spread spectrum so proving interference will be nearly impossible for the suffering ham.

I too have had valuable packages left unattended on my doorstep by UPS; some of them were even mine!

Also, I live on a private (dirt) road that is on an easement across my property. Under Arizona law, I get to be the traffic cop, and for dust control, I have posted a 10 mph speed limit. The &@!Y#&* UPS trucks do about 35 when heading to my neighbor's place. I have stopped them and asked them to keep the speed down. One the guy said, "Sure thing" and then took off leaving me in a cloud of dust.

I called UPS to complain and was told that a supervisor would call back in within an hour. That was about two months ago and I'm still waiting.

So.... the next time, I'm going out and locking my gate across the road after the truck has entered. I'll unlock it after I get that call from the supervisor.

A good guess for the material would be PTFE (one of the Teflons). Its dielectric constant is 2.1. Another possibility is polyimide (Kapton), with dielectric constant of 2.8 - 3.0. Teflon is soft and stretches easily. Kapton isn't and doesn't.

I have no practical experience of any of the antennas in your list but, off the cuff, I suggest the following guidelines.

If there's a fixed value loading coil somewhere in a short mobile antenna then its good for only 1 or 2 bands. It may be excellent on those 1 or 2 bands but is likely to be useless on all the others.

The tallest antenna will ALWAYS have the highest radiating efficiency, everything else being equal.

An antenna which has a long, continuously variable loading coil, such as a 'screwdriver motor' type will maximise efficiency on all bands it is specified to cover.

Everything else being equal, the antenna with the fattest diameter loading coil and the thickest diameter wire will have the highest efficiency.

For good efficiency on all bands, consider an antenna which has one loading coil which has to be changed for different bands. Inconvenient of course but they do work.

Concentrate on efficiency of the lower frequency bands. The highest frequency bands, 15 and 10m, will look after themselves.

But where an antenna is located on the vehicle has a greater effect than any other consideration. Far and away the best location is in the middle of a tall vehicle roof.

An antenna's mechanical robustness and long-term reliability can be judged only from a visual examination. But the long-term may not be very important. Most amateurs start thinking about trying something else after the first 100 miles.

Considering the cost of system as a whole, don't skimp on the tuner. Tuners on the lower frequencies should have fat coils of thick wire just like those in the antenna.

Happy motoring !

A tree is cheap, but the installation time is about 15 years.
<grin>

I had basically the same problem a number of years ago, Steve.
What I did was build a wooden platform as part of my daughters
playground set I built and bolted my 25' mast to it. I had a 4
element 10 meter beam on top of it and had no problems. The
platform was built from 10' 4x4 posts in concrete and the platform
was at the 6' level and was made of 2x8. So the whole structure was
pretty solid.

What I have done more recently was take a corner 4x4 fence post
(in concrete) and bolted a 22' mast to it. I had a 2 meter vertical
on there for awhile but moved that to a chimney mount on top of our
second floor roof, which gave me a little more height. The mast is
now the center of a 80' meter dipole. I've been wanting to put up a
another mast, but like you, I can't guy it. I can guy it on two
sides but not the third. So I've been thinking of putting a 6x6
into about 3 feet of concrete and 8 feet above ground and bolt a
mast to that. On this mast I'd like to put a small tri-bander at
about 20'. I'd like to put up a tower but we might move in the
near future and it will be easier to get a post out of the ground
than it would to take down a tower.

Anyway, you might look into using a post for support. It might
work for you.

> ============================
Hello old man,

I'm not familiar with your Nye Viking tuner. But if it is designed to accept a balanced feedline then an external balun of any sort is not needed of course. There must be one inside the tuner already even if it is in the form of a link coupling.

I mentioned it because most tuners are unbalanced at both ends and the most simple, economic and efficient means of connecting the balanced line is via a choke balun. Neither of the pair of line wires is then grounded at the tuner terminals.

Construction can be just 8 to 16 turns of a pair of 18 or 20 gauge wires, like twin speaker cable or similar, wound round a ferrite ring.

A choke balun is not an imedance transformer. It is just a bifiar-wound choke. Its input impedance is practically the same as the impedance it is terminated with. Its purpose is to force the currents in the pair of line wires to be equal and oposite to each other. ie., there is little or no longitudial current in the line when the two wires are considered to be a single wire. Radiation from or pick-up on the feeder is then minimised.

Because it is not an impedance transformer, a choke balun may result in inconvenient L and C settings in the tuner. In your case, the internal balun is probably a true impedance step-down transformer from 450/4 = 113 ohms. Or 450/9 = 50 ohms. This is nearer to 50 than 450 and so the tuner's L and C values may be more reasonable.

Bear in mind the impedance looking into the 450-ohm line is 450 ohms only when SWR on the line is 1-to-1 which it never is. A choke balun is much more accommodating to wide swings in line input impedance than 4:1 or 9:1 true transformers.

As I suggested earlier, you have found a high centre-fed dipole, fed over a balanced high-impedance line all the way to a good tuner in the shack, is the best possible all-round, multiband antenna in the book. Few people fully appreciate this until they have tried all the many other wierd contraptions. Should novices be restricted to short lengths and low heights alongside their radiated power limitations ? ;o)

> >dipoles?

The following is some of the info I gathered in my attempts to understand and build a Lattin. As I said in my previous post, I was never able to get it to work as Mr. Lattin described.

It has been patented, filed Feb 13, 1948. Patent # 2,535,298 My local library had the patent on microfiche, and I was able to get it copied. I have a copy of his patent, with illustrations/drawings, on file here.

Lattin described this antenna in QST in December of 1960.

July 1960 issue of "CQ" mag has a related antenna project, by Richmond, W1CEJ, called "A Portable Dipole"

Vincent Lear, G3TKN has also worked with the Lattin design, and was published in RSGB.

July 1992 issue of "73" mag has another article "Six-band linear trap antenna" by Brumbaugh KB4ZGC.....using approx the same idea.

September 1986 issue of "73" mag has Lattin type antenna project described...."The Texas Tango Antenna" by Garrett K5BTV.

Maybe the above info will stimulate some more experimentation with the Lattin. I sure hope so.

Which is really scary - as Ford Motor products are more reliable than
General Motors products, these days.

It's hard to say. You may be fairly well grounded. I have done just that on my truck, except I haven't really had a chance to test it yet. I got some sheet metal to make a plate to cover from the bed lip back about 2 ft or so. I'm hoping it will help a bit. I still think I need to move the antenna though. I mainly noticed it on 75m. I've never had the performance on that band so far, that my car does. But strange enough, 40m up seems about the same as the car. Or at least good enough to not notice much difference. 40m does quite well in the truck, although I think it could be improved if 75m is suffering. I want to put a camper on the truck eventually. That will further complicate things unless I get an all glass top. MK

They do, but I think the performance increase per spoke drops off
fairly fast as you add more. But I may be wrong on that. I hardly use
hats, so don't get much practice messing with them. All my "hats" go
straight up. :) MK

You can buy/make/have-made wall mount brackets that will hold the mast
3 feet away from the wall.

A 20 foot mast that will support a fringe antenna plus an HF vertical
is going to have to be rather robust - seeing that you want it to be
self supporting. It would also require a fair amount of concrete in
the ground.

I haven't tried it, but plan to. Since authorities here say that the area between the
conductors is what causes the problem when wet it seems that running the ladder
line through a plastic tubing or pipe should solve most of it. Any version that the
ladderline will fit inside should do it.

They don't have to be separated by any certain degrees, just
make sure they don't lie together. Separate them by as much as you reasonably
can, hang them where you can, like most
everyone else does, and have at it.

That seems to mean that without advanced math and engineering training and
skills
one can't understand concepts and relationships, and successfully work with
them.
I find that to be not the case at all, as one who has worked and played in
radio and electronics for the past 45 years without either.

I always found that only a basic grounding in mathematics necessary to design or repair circuits. I am by no means good at maths and luckily for me I have never found it necessary to use phasor diagrams, simultaneous equations etc but it would certainly have been nice to have been comfortable with them. I think people who come into the trade as they leave school do very well to learn the trade and forge a career out of electronics. I was lucky enough to have been curious since I could crawl, and I don't think I would have stood the course if I'd had to learn it all at school. I guess I'm like a lot of other people who love electronics and hate maths, and it certainly discouraged me from studying the subject at college.

Could you please tell me where to find this text?
I've started to collect information from local experts (electronic and telecommunications engineers and physics other than hams) to set up a very well organized test.
Here's how we intend to proceed:
We already have located the place for the test, you can have a quick glance at: http://www.virgo.infn.it/
We selected this site since it's a very large flat site and one of us has access to this site without problems.
We intend to test the EH antenna (brought by Stefano himself) against a vertical half wave radiator (in the 14 MHz band) and against a commercial dummy load. The receiving station will be located at about 4 Km from the transmitting station. The receiving station will have a short vertical antenna (0.5 to 1 meter long) to approximate an isotropic antenna. The receiver S-meter is calibrated with HP instruments and however we have the possibility to use well calibrated attenuators with 1 dB step.
There will be no obstacle between the receiver and the transmitter and in the near 6 Km radius.
We of course will place an RF choke in any transmitting or receiving antenna.
Other details are still under discussion and will be "broadcasted" here once we define them. We hope to be ready for the test in few weeks (mid to end of february we hope) as we would like to have the support from a certain number of hams and researchers that come from different places in Italy (anybody is welcome, please contact me privately if want to join).

> Please keep us informed of all development.

I will for sure.

best regards.

You don't need to rise from your chair to review a patent. US patents (text and/or images) are available on-line at: www.uspto.gov .

The patent images are TIFF files - a virgin browser may not be able to view the images. The QuickTime plug-in (very common and readily available) seems to allow viewing of TIFF images. There are other options. I just had a quick peek at that patent - took 30 seconds.

1886. Antenna Ground installation questions

Message-ID: <a33h6r0ncd@enews3.newsguy.com>
Source record: 149924

I have just installed a Kenwood D700 in my truck and have also purchased a home base antenna so I can bring the radio inside as a base unit from time to time. My antenna is a dual band cushcraft (used). I will be able to mount the antenna to a tripod on my roof which is currently used to mount my weather station gear. My question is mainly about grounding. The tripod is grounded to a ground rod already. What further grounding is needed? Do I need to ground the coax at some point before entry into the house? Or perhaps put a lightning arrester in the line at the entry point? Any suggestions here are welcome. I have searched the internet and this NG but I am still not clear on proper grounding techniques.

Keep any eye out for any good-sized hamfest near you. Usually there will be
at least one person selling "surplus" telescoping masts in the 30-40' range.
Often these can be had for $50 or less.

hey tim
if the tripod and mast are grounded the antenna will be grounded as well when you stick it on the mast
you will get a lot of people telling you to put all sorts of lightening protection inline but i can tell you that if the lightening wants your gear its going to get it anyways
what i do down here in florida is make sure the antenna is grounded and disconnect the rig when there is a storm brewing up or when the radio isnt in use and i have never had a hit
good luck

Some people run a static discharge unit on the coax to bleed off any static
that is building up on the antenna. This protects the radio and "lessens"
the chance of a direct hit. This unit will NOT however protect the radio if
there is a direct hit.

While it's true that there's little we can do against *direct* lightning strikes, there is a lot we can do against voltages induced by nearby strikes and against static buildup. That's what "lightning arrestors" are for. Read the ARRL handbook on the subject of grounding. Basically it tells you to use a lightning arrestor on each line coming into your house, to ground them *outside* the house at the entrance and to bind that ground to the electrical service ground. They also suggest using some sort of interruptor *outside* the house to disconnect everything when the radios are not in use.

I would like to put up an inverted L with the vertical section attached to my house (standoff insulator with insulated wire) and the horizontal section going from the house to a tree in the back yard. My question is whether the siding on the house will screw-up the tuning of this antenna. I will only run low power, 10 watts or less, thru it. Any suggestions on comments.
Thanks - Scott W3BUG

Source record: 149938

Scot, go right ahead. The only effect of the aluminium siding of the building will be to screen the antenna a little more than if it was a timber or brick building.

It will not increase antenna loss when transmitting. Aluminium is a low-loss conductor. It may even reduce the small loss which would occur in a brick building.

If you can, connect the siding to ground.

The effect of adding spokes on field strength is somewhat similar to
the effect of adding elevated radials to a vertical. IMO, the effect
of doubling the spokes from 4 to 8 is worth the effort and 8 to 16 is
probably not worth the effort.

Hmmm,
except maybe Explorers? Editor of Machine Design magazine related his experiences with Explorer - Firestone tires problem: Ford messed up suspension design and mandated that tires be underinflated to around 26 psi, that combined with Firestone glue problem, extra overheating due to flexing appears to be the cause of many fatal crashes. When he inflated tires to 32 psi and tolerated "hard" ride, no problems at all. I haven't seen this mentioned in the media.

Back to:
Do EE majors make better Hams?
I think Hams make better EEs or anything. Being serious and curious Ham is indication of person having much more than complacancy of just doing its job. I haven't seen any EE majors mastering contesting or beating this ME :-) But I would not be happy to combine my professional work and hobby. I have seen many hams go QRT after getting into professional side of EE (ham radio business). I need the change or switchover to something else when I quit working, I can't picture myself working and hobbying at the samething.

American car and ham radio loving mechanical MSc.E.

Electrical Engineering Institutions began in the Victorian age. In the UK it
began mid 19th century with Professional Telegraph Engineers.

But in those days it needed an EE to change an electric light bulb !

>Have any study been done on this? I'm surprised that the ARRL hasn't
>researched this. (Or have they?)

I gotta hand it to you Jason, you really know how to pick interesting
subjects for a thread...

I've done exactly what you wrote about. I held an Extra Class License
before I went to college and I later got my EE degree.

Ham radio helps, but it also gets in the way.

If a person is generally curious enough to experiment with circuits in
ham radio, then they learn something as an engineer. If they're
mostly in to *operating* the radio instead of building one, it really
doesn't add or subtract a single thing from their education.

I tinkered with circuits. I learned all about decoupling the supply
lines to an amplifier. I knew what parasitics and motorboating were.
On the other hand, though I knew what a filter was, I had no idea how
to design one.

Then I went to school. Most of the students in my class had no idea
how to solder, how to use a 'scope, how to use a volt meter. I had my
doubts after graduation how many really understood what they did in
their labs... Schools are good at laying the theoretical foundation,
but they will always stink at practical applications.

This is where ham radio gets in the way. There are classes when you
really have to park your brain away from past experience and just sit
down and pay attention. There is often a lot of formality of approach
to some silly subjects. For example, I've never seen a more
convoluted and obtuse description of positive feedback though a poorly
decoupled power supply as I've seen in my circuits class. And the
mathematical treatment was something I felt at the time was nearly
pointless (I've learned better since then). My experience as a ham
was "just stick a cap across the supply line and see if that fixes the
problem." This makes it awfully hard to sit still and pay
attention...

I have to add that I also had substantial work experience as an RF
technician. Having a background that connects and intersects with
your subject matter usually helps.

The bottom line is this: Chance favors the prepared mind. If you're curious, if you're interested, if you're looking for the opportunities to connect your ham radio experience with what you're studying, then you will become a better engineer and a better ham for having done so.

That can be said, no matter what your interests are.

Incidentally, while I've noticed that although many hams are good electrical engineers, that's no guarantee. I've known some particularly useless engineers who coincidentally were hams as well. It's a positive indicator in most cases; but it's only one potential indicator of interest out of many, not a proof of performance.

Good observation. I'm beginning to wonder if all the efforts we put into resonating antennae are worth the bother. I installed a used ($80) HF6 on our roof for easy access to the shack, driving it with the proscribed 75 ohm section cut per the manual and another 10 feet of 50 ohm coax. I started out using 4 TV twinlead radials also cut per the book and have since added many more wires cur to length, trying to lower the SWR to no avail. OTOH, the XYL has worked everything from the Urals, Antarctica and Oz on 100 watts using an antenna tuner. I keep thinking I can "improve" the SWR but she's began threatening to kick the ladder over if I try on the theory "Don't fix what t'aint broke".

You should find out/verify what is the radiation pattern of "miracle" antenna and try to select comparison antenna with similar pattern, so the lobes are approximately, or as close as possible. I.e. comparing the same dipole antenna vertically and horizontally polarized would give you completely different results (depending on height) if measured with RX setup at the ground level.

For example, two element vertical array at the beach would beat high 6 el. horizontal beam at low angles, at the beginning and closing of the band openings. Vertical like that produces more signal at the horizon and low angle than just about any horizontal antenna.

Make sure you test and compare apples and apples. If the antenna is vertically polarized, then the best way is to test it against good ground system of radials or counterpoise and switch the antennas under test. Otherwise widely separated two of the same "ground" sites would do and allow live comparisons. Live tests on the band with various angles of propagation would be also good indication of antenna RX and TX performance.

Just wanted to get opinions on what KW dummy load to purchase. I am from the old school and have used the old Heathkit oil filled dummy load many years ago. After being off the air for many years I need to purchase a new one. I see that MFJ sells an oil filled one but are there others or other types that I should consider? It must be able to handle a KW on HF. Of course low cost is a consideration.

Thanks

Yes, I'm aware about this. However, how would you find out the
radiation patter of the "miracle" antenna if nobody has a clear idea about
it? Anyway, it should be vertical polarized in my (and others) opinion,
that's why we're going to use a vertical end-fed half wave as reference.

> For example, two element vertical array at the beach would beat high 6 el.

I agree, as I said I believe that EH radiates a vertical polarized field.

> Make sure you test and compare apples and apples. If the antenna is vertically

Yes, sure. I selected an end fed half wave antenna because it is largely
independent from the ground.

> Live tests on the band with various angles of propagation would be also good
> indication of antenna RX and TX performance.

Well, I believe that we'll try also these kind of tests, but the main test
will be focused on TX performance against an half wave antenna with the
same polarization.

Thanks and 73.

| I haven't tried it, but plan to. Since authorities here say that the area
|between the
|conductors is what causes the problem when wet it seems that running the
|ladder
|line through a plastic tubing or pipe should solve most of it. Any version
|that the
|ladderline will fit inside should do it.

This seems like a heroic effort for little payback. It seems to me that some of the advantages of window line (lower cost and weight) are defeated by going this route.

Furthermore, I believe that it is the presence of water in the electric field that exists between the conductors that causes the increased loss. The fields are not totally confined to the space directly between the conductors; if they were, we could bury the line or strap it to the side of the tower. Consequently, water on the surface of the PVC tubing (unless it is very large) will have a similar, albeit reduced, affect on the line attenuation.

Furthermore, I believe that those of you living in swamps will have a problem with condensation inside the pipe anyway. This will give you the balanced line equivalent of the "water-in-the-coax" syndrome.

Leland Cox wrote:
"Was there such a thing as an EE in 1920?"

Electrification began in the 1800`s.

To get the most for electrification effort, a hundred or more years ago, required some knowledge of electricity, practices used to exploit electricity, materials used in electrical practice, and how to calculate the quantities, sizes, etc. of everything needed, just as it does now.

By 1920, electrification was well underway thanks to engineers who could make the necessary calculations and knew how to apply them.

Radio was well developed. Ed Laport has a nice bibliography in "Radio Antenna Engineering" on antennas and radiation theory. It has entries at least as old as: S. Ballantine, "On the Optimum Transmitting Wave Length for a Vertical Antenna over Perfect Earth", Proc. IRE, 12:833, December, 1924.

The ARRL was formed in 1914.

In the year 2000, "The Institute", from the IEEE, reprinted Neil Armstrong`s opinion of the 20 most significant engineering achievements of the 20th century:
1. Electrification
2. Automobile
3. Airplane
4. Safe and Abundant Water
5. Electronics
6. Radio and Television
7. Agricultural Mechanization
8. Computers
9. Telephones
10. Air Conditioning and Refrigeration
11. Interstate Highways
12. Space Exploration
13. Internet
14. Imaging Technologies
15. Household Appliances
16. Health Technoligies
17. Petroleum and Gas Technologies
18. Laser an Fiber Optics
19. Nuclear Technologies
20. High Performance Materials

For sure, the priorities won`t be the same in the 21st century, and many will disagree with the first man to walk on the moon as to the order and importance of developments in the 20th century.

Best regards, Richard Harrison, KB5WZI

With the high dielectric constant (80) of water it is likely the decrease in line Zo has as great an effect on tuner settings in heavy rain as does an increase in line dB. It may even be the dominant factor.

Things may not be so bad as is generally thought. When it rains I just readjust the tuner a little to return to 1-to-1 SWR.

Only when steam can be seen rising from 300-ohm ribbon line should anyone start worrying about loss in signal strength.

Steve:

I had not read your inquiry carefully until this morning. Here is how I once did it in the same situation (3 foot eaves). You need 4 items, a 4 or 6 foot piece of treated 2X4, a 20 foot joint of 2" or larger chain link fence post, and 2 lag bolts. Lag bolt the 2X4 under the soffit to a rafter extension with it sticking out past the eave, cut it off at the length you want, and U bolt (whoops, that's 5 items) the post to the 2X4. Put a good base under it which will support it and keep it from shifting. I usually used a brick with holes in it, and a piece of 1/2" or larger rebar driven in the ground.

First, did I direct it at you? No, so butt out.
Second, I responded to abuse, there was provocation, for heavens sake. I
over reacted, I APOLOGISED!! You are not helping anyone by dragging the
matter up again. My apology should have put an end to it, but I can see
there are some unreasonable people out there.
Thirdly, JW can fight his own battles. Are you his keeper or his nanny? I
wait with bated breath to see how people on this NG respond when baited

which regrettably caused me to lose it. I guess I'm the only person who should tolerate unprovoked abuse? It isn't going to be like that. Now I have already apologised and because you are trying to stir things up, you don't look so good yourself. Get out of my face please.

The thing that amuses me most about this thread is how people like to judge others based on the aspects of themselves where they consider themselves to be particularly experienced, knowledgeable or an expert.

In general, most motivated people excel in areas that interest them. I would expect that whether or not a ham is a better EE student probably has more to do with his/her character, level of interest, level of motivation, desire to learn and intelligence; than whether or not they have a call sign or can solder better than their fellow students.

As for the "practical" nature of an EE degree, how many people really believe that they can judge a person's skill, knowledge or intelligence based on a specific four year period of that person's life? Is there anyone on this NG that stopped learning when they were 22 years old? My EE degree provided me with a very solid theoretical and practical background (we learned to solder, use scopes, build antennas, test antennas, etc where I went to school) that was just the beginning of my learning experience. I have and continue learn more each day (I hope).

In all fields of endeavor, there will be all levels of competence and incompetence on an individual basis. The factors that affect this aspect of one's person are generally more deeply rooted than whether or not that individual has a four year degree.

The quality of education at our higher institutions of learning is another subject on its own.

I don't think so. I have measured, albiet as an afterthought, the parameters of
wet window line. There is a small effect on the Zo and Vp and a much larger
effect on the attenuation.

(See: http://users.triconet.org/wesandlinda/ladder.htm
and look for the link to "Balanced Transmission Lines in Current Amateur
Practice")
|
|Things may not be so bad as is generally thought. When it rains I just
|readjust the tuner a little to return to 1-to-1 SWR.

Wait a minute! I thought you didn't believe in SWR <g>.
|
|Only when steam can be seen rising from 300-ohm ribbon line should anyone
|start worrying about loss in signal strength.

I'm sure your tongue is firmly planted in cheek, however, this is akin to the
idea that the losses in tuners can't be too great because they don't burn up.
Unfortunately those proposing this idea completely neglect the low duty cycle of
amateur transmissions.

The same page above has some correspondence ("a letter to Dean") where I
addressed this issue quite sometime before ARRL started publishing papers on the
measurement of tuner losses. Coincidence?

Some people do indeed live in a swamp, even if it is Roy's cold swamp.
We sometimes get plenty of rain here in East Texas and I haven't had
any moisture problems. The way I tune my antenna system is to vary the
length of the ladder-line. On 40m, there is only one foot difference
in the resonant length when it is raining and when it is not. That
tells me that the rain has little effect on my feedline system. The
probable reason for that is that my ladder-line comes directly
vertically down from the dipole to the eave of my house. The remainder
of the run to the shack is under the eave out of the rain. Thus I
don't have any horizontal runs of ladder-line that can get wet. I
only have about 30 feet of vertical ladder-line that can get wet.
So I don't think short vertical runs of ladder-line are a problem
in wet weather. Long horizontal runs of ladder-line are obviously
a problem. Trimming away the excess insulation between the wires
might help.

I've just ordered 150 ft of the 600 ohm open-wire line from W7FG. That
should minimize any moisture problem. Roy, have you tried your
balanced line experiments with open-wire line?

Anyone have a balun design with 50:100, 50:50, 50:25 ohm taps?

Steve, VE9SRB wrote:
"The thing that amuses me most about this thread is how people like to judge others based on the aspects of themselves where they consider themselves particularly experienced, knowledgeable or an expert."

Best foot forward (no pun intended)?

It is funny because being good with numbers or a soldering iron doesn`t make anyone the best person. Life is much more complicated.

The funniest thing about this thread to me has been the denial of conventional wisdom. The market for the incredible among those who want to be gullible is big. Sales of pulp magazines, with stories of alien abductions etc. are good.

In this thread there has been a receptive audience for:
1. Amateur is better than professional.
2. Trial and error are better than calculation.
3. A technician is better than an engineer.
4. Engineers can`t solder.
5. A low grade point average is better than a high grade point average.

Continuing a list of alleged paradoxes is unnecessary. An exception does not disprove a general rule.

Pretenses should not be necessary to feel valuable. Everyone has worth. Pretenses lead to disappointment.

There is an expression: "Everyone is ignorant, it`s sometimes just on different subjects."

Just about any Dummy Load will take a KW. Question is for how long, and at what duty cycle? I'd stick with the Oil Filled types for low cost. The Heath one can still be found for $25. A couple minutes of Key down should be plenty for any dummy load application. I suppose you could make the Heath Cantenna into a heat exchanger, hook it up to the garden hose, or pack it with ice for longer Key Down testing.

Not always. Perhaps "especially when it is sand" would be more
true. Saturated silt will be a lot MORE dense when it settles. You
can easily see this in a glass. The issue is particle size. Larger
particles will leave more air gaps. Fines will not. Larger
particles will settle to the bottom, fines will settle on top and
gradually sink down over time (water your ground rods regularly).

> else commented on. There have been measurements made of contact resistance

The NEC does not always require a driven rod. The NEC is not
concerned with ground quality (e.g. drive one rod, if it doesn't
test well, drive another, no second test required).

No, but Wes Stewart did. You can see his results at http://users.triconet.org/wesandlinda/ladder_line.pdf. At 50 MHz, the loss went from about 0.4 dB/100' dry to about 6 dB/100' wet. I've gotten as far as purchasing 100' of ladder line, but haven't run any tests yet. I'd like to run tests with a setup similar to the one I did with twinlead many years ago and see how my results correlate with Wes's.

Late last year we tied our local record of 32 successive days with measurable rain. In the wintertime, though, most things never really dry out between showers, so nearly everything outdoors stays at least damp from about October through June or later.

When I caught glimpse of the studies performed there, Gravity waves,
it was like deja-vu all over again (I've researched this topic for a
super-conductor manufacturer). However, it does give every appearance
of the terrain Jack Belrose chose. You might want to do an RF
background noise test just to confirm the local scientists won't cause
confusing signals. It seems unlikely given the nature of the
instrumentation and their claims of quiet environment. In that

regard, you need to seriously consider how much your experiments may intrude on the operation of their system.

>We intend to test the EH antenna (brought by Stefano himself) against

>isotropic antenna.

Look into the Inverted F at:
http://www.qsl.net/kb7qhc/antenna/Inverted%20F/index.htm
(not that I think it would offer any advantage)

You might want to try a vertical monopole the same elevation (above ground) as the EH with the monopole as tall (same height) as the EH. After-all, the proponents suggest the EH should be better in performance; otherwise there is no commercial advantage for the EH given the complexity of construction and difficulty of tuning the EH over this simple alternative.

I say this because you will be measuring the ground wave (line of sight too) of a 20M source. I would suspect that comparison to a standard vertical at this high frequency changes the mechanics of propagation sufficiently to make this a new ball game. Commercial claims are at 200M, Jack tested at 80M and you guys have cut that by a fourth to a tenth with 20M.

>The receiver S-meter is calibrated with HP instruments
>and however we have the possibility to use well calibrated attenuators
>with 1 dB step.

Using only the S-meter has very little value for serious work. Roy has often suggested one of the more accurate means for using an S-Meter for comparisons. That is to place a calibrated step attenuator in the receive antenna path, but only in that portion of the line that is matched to 50 Ohms. This means you MUST match the receiver input to the sense antenna, and both MUST present a non-reactive 50 Ohm system to the inserted attenuator.

Set the attenuator to a value that is NOT 0dB insertion loss. Run a test signal between the antenna under test and the sense antenna to find an S-Meter reading that is both repeatable and presents the greatest variation in meter needle swing for, say, a 1dB change at the step attenuator. The problem with this method is found in the sensitivity of the meter. It varies along the scale which should be entirely ignored beyond the s9 = 50ï¿½V specification.

The technique here is akin to the balance of a bridge, but this simplistic analogy hides the fact that balance meters are extremely sensitive and this method that attempts to mimic it is generally suitable only to the first pass test. The test I describe in the paragraph above seeks to find the most sensitive relation between the

meter and the variation of 1dB somewhere in a continuum of power
levels (this is why you start with a non-zero dB insertion loss as
this may have to change widely too).

When you find this "sweat spot" where the meter is most sensitive,
mark it so that the setting (your reference) can be recovered through
the manipulation of the step attenuator. At this point you have
reduced all the variables of the measurement to the minimum of those
introduced by the step attenuator, and the operator's ability to
return to that reference mark. The degree of resolution in the
measure is a function of the meter sensitivity. With luck, you might
get 0.5dB resolution (not to be confused with accuracy).

>Francesco IZ5DWF

Hi Francesco,

More considerations to observe:
One measurement is meaningless;
Two measurements is confusion;
Three measurements will give you an approximation;
Five measurements begin to give you accuracy.

Discarding the high and low readings is generally acceptable for more
than five measurements, but only if they are obvious outliers.

Once you have performed at least five measures (this means a complete
break-down and reassembly of the test configuration each time),
reverse the two (sense and EH) antenna's positions and repeat the test
suite again. Hopefully this will balance the site's bias toward one
configuration over the other, if indeed there is a bias. However,
this is not sure, and you should also attempt to rotate the path by 60
to 120 degrees and repeat the two test suites of five measurements
once again. This path rotation should reduce local perturbations to
the results.

Repeat for the sense and Standard antenna.

You should note that the number of measurements is now up to 40. Given the growing number, I would suggest DO NOT repeat measures in place, but rather swap sites, and/or rotate sites between EVERY measurement to fill in the test grid of 40 measures. This may seem excessive, and for the purposes of amateur activity I would offer that you could get by with 20 or so. Any less comprehensive test scenario will not be very compelling even when the numbers are obviously separable between the two (the EH and its substitute).

If this still seems overwhelming (Metrology is NOT for the anxious), you might get away with boxing the compass (forgive my language play; that is: rotating the path described above) and taking as little as 8 measurements WITH NO REJECTED DATA. I must caution that those 8 numbers will have to be clearly separable to justify this small survey. The advantage to the rotation is that you can quit with 8 when it becomes obvious 40 would only provide redundant results.

So much for method. Now to accuracy.

You MUST exhibit at least 10dB S+N/N under all circumstances; and only for highly separable data. 20dB is preferred. As this style of measurement is generally known as the substitution method, once you drive out the controllable sources of error (like front end overload, poor meter sensitivity, local field perturbation, lack of symmetries) your step attenuator is the determinant of accuracy. This device is easily calibrated and verifiable - even if it is a homebrew! The substitution method is one of the most powerful ways to obtain precision and accuracy (and in fact is the basis of the test at the larger level between the EH and the Standard antennas).

Now for an alternative for more precision.

There are far more sensitive methods for measuring than the one described above (which is probably adequate). This variant I will offer allows you to skip the requirement for matching the receiver (an absolute necessity above). There are many instruments that are based around 1000 Hz tuned detectors and bridges. The variation would have you modulate the transmit signal with 1000 Hz and use the step attenuator at the audio output where you can use some of this tuned instrumentation. The tuning allows you to reject interference (razor sharp in comparison to the original method) and gives you access to meters of far more sensitivity (often orders of magnitude more sensitive). The methods described above differ only in that the step attenuator has moved. As such ALL considerations MUST be met. For this variant, you might want to use a step attenuator with 0.1dB resolution. With some instrumentation, this step attenuator function may be found in the instrument's own range switch. Further, such instrumentation may allow you to make a direct difference measurement instead of performing the substitution to re-achieve the reference mark; however I would still use the substitution method as there are a lot of variables that could muddy the water for direct measure.

Now. as to terms employed (they DO NOT all mean the same thing):

Resolution:
The number of places you can make a measurement to. For example, most meters have major and minor gradations. Resolution in this sense is to one-half minor gradation. Some examples are obvious like the reading of a frequency counter 1.000000 MHz (resolution is 1 Hz). Same for a DVM. In this sense it is more correct to say parts per million or to describe it as a 2000 count meter (the display will read 0.001 to 1.999)

Precision:
This relates to resolution in most people's minds only because resolution reveals precision. Precision is the ability to make a repeated measurement without too much variation between readings of the same value. To be precise means to be able to repeat to within minor variation of the resolution (hence more precision demands more resolution).

Accuracy:
This is always with regard to a "known" value. There is no such thing as accuracy without an attending statement of variation from "known." ALL accurate measurements contain a statement of the bounds of error. For a 1.000000 MHz source measured to 1.000000 MHz ï¿½0.100000 MHz, this is highly resolved, but of no remarkable accuracy and obviously all over the map with regard to precision. If I were to observe 1.000000 MHz +0.100000 MHz consistently, it is highly resolved, very precise, and highly accurate even though in apparent error of 10%.

You who are about to measure - we salute you.

There are engineers who are only engineers, then there are technicians who are only technicians, there are also engineering technicians, and finally engineers who are are also experienced technicians. Some overlap is inevitable. Some of each are also hams.

Source record: 149967

I really wish I could join you -- the experiment is bound to be very interesting and educational. May I make a few suggestions:

1. Provide a way to measure the current on the outside of the feedline. It's easy to do -- put a high-permeability ferrite toroid (such as type 43 or 70-series) over the coax. Wind a ten turn secondary, connect the secondary to a piece of coax to run to a scope or meter, and terminate it with 50 ohms. The current on the coax in amperes will be 2 * the voltage across the 50 ohm resistor. You can check the calibration if you want by putting it on one leg of the reference dipole, near the feedpoint, where the current will be known, given the impedance and applied power.

2. Besides the comparison with the half wavelength vertical dipole, compare the EH antenna to a short vertical antenna placed in exactly the same position and fed with exactly the same feedline. A fat vertical would be appropriate.

3. Disconnect the "D plate" or whatever the equivalent is in an EH antenna, like Trainotti did, and see what happens to the signal strength.

4. Take lots of notes, describing everything you can. Take lots of pictures, too, if you can.

5. Make lots of measurements. The more, the better.

6. Try to anticipate what criticisms could be made of the measurements, and devise your tests to minimize these.

Some criticisms of previous measurements of the CFA are:

1. Assumptions are made about the ground conductivity to determine what the field strength from a quarter wave radiator would be. The way to avoid this criticism is to make measurements of a quarter or half wave antenna at exactly the same position as the EH antenna, within a short period of time, so the ground conductivity is the same for both.

2. Feedline radiation. You'll be using baluns, and should measure the current all along the feedline to make sure it's negligible.

3. Poor knowledge of the actual power being supplied to the antenna. A directional wattmeter should prevent this problem.

4. Measurements at only a few field strength points. It's well known in the AM broadcast industry that measured field strength can vary considerably from point to point, and not follow theoretical curves, often due to reradiation from such things as power poles. Consequently,

broadcasters make many measurements at many points. You should do this if possible. If not possible, then it's even more important that the test antenna and reference antenna be positioned at exactly the same place for the measurements. If it's not possible or practical to position the antennas at the same place, then what you should do is make the measurements, exchange the antenna positions, then repeat the measurements. Don't be satisfied until you get very close to the same results with the antenna positions reversed.

We're all looking forward to seeing the results of the tests. Thanks to all for making them possible.

When the tests show that the EH antenna works as claims, you shouldn't have any trouble finding an investor to put up the money for some more elaborate tests at a certified test range. And after those results come back and are published, it won't be any time at all before the EH inventor and supporters are rich beyond imagination.

Wes, do you think the increase is loss when wet is due to increased dielectric loss, or due to increased conductor loss because the water is attempting to carry some of the line current ?

I note your measurements were made at 50 MHz. How much smaller would be the effects at frequencies where such lines are actually used - say 3.5 or 7 MHz.

Reg.

I have one, and on a balance of efficiency, ease of frequency/band change, and general power
handling capability, it's probably my BEST overall antenna... But on the OTHER hand, for pure
efficiency on any SINGLE band/frequency, something like the "bugcatcher" antennas are the best out
there - all other issues being equal...

For benefit of credibility, I have used Hustler, SGC autotuner, Hamsticks, Master mobile, and a
whole PILE of custom-made homebrew stuff...

OH, by the way, screwdriver type antennas ALSO top the field in UGLY and difficult to properly mount
as well... :-)

Source record: 149880

Do EE Majors make better hams? I asked my good friend Andy Rooney, and here's what he said:

Well, to begin with, the terminology in the question is both silly and unclear:

By "make", does the question mean to "construct", "manufacture", "identify", or "have sex with"?

By "EE majors", does the question identify persons currently or formerly in engineering school? Did they graduate, take to drink and flunk out, or escape to the English Department in order to indulge a fetish for filling blue books?

Exactly what would a "better ham" do to alert us to his or her superior "hamliness"? How would we know "better ham" if we saw it?

As one contributor suggested, perhaps engineering requires a level of rigor some might not enjoy. For example, a more rigorous question might read:

Are there clearly definable markers or traits held in common that might predispose persons engaged in the study of Electrical Engineering at a college or university to also exhibit and perseverate at behaviors identified and widely accepted as indicators of superior knowledge and skill when participating in the hobby of amateur radio?

If you're comfortable with that line of rigor, you'll get to study the rats. If you're not, you'll get to clean up after them.

On 40 meters and up you can get good results with either the
Hustler setup or Pro-Am brand hamsticks (they are more
rugged that others I've seen). Bugcatchers and screwdrivers work better
but not enough better to warrant the extra expense and trouble unless
you want to change bands from the driver's seat badly enough.
Nothing (conventional) works well on 75 or 160..

I believe it is dielectric loss. The "open-wire" control sample I measured was
not affected at all by wetting the wires. Of course very little water actually
"stuck" to the enameled wire.
|
|I note your measurements were made at 50 MHz. How much smaller would be the
|effects at frequencies where such lines are actually used - say 3.5 or 7
|MHz.

Well, if you go back to my page and read the "Update" part, you will see that
Dan Maguire, AC6LA, and I did some additional work (using the original raw
measurement data) and came up with loss coefficients that can extrapolate the
results to any (reasonable) frequency.

If you believe that the data I presented in the original paper for the wet line
condition are accurate then you can assume that the conductor loss coefficient
is fixed regardless of whether the line is wet or dry and solve for the
dielectric coefficient. Dan's Excel solver will do this for you. With both
numbers at hand, the attenuation at a new frequency can be estimated.

If, like me as I suggest in the "Update", you are somewhat suspect of the
accuracy of the original (wet) data, then "estimate" is a better word than
calculate.

Once again I would like to state that these "wet" data are probably close to the
worst possible case and not something likely to be encountered in the real
world. They do however backup anecdotal evidence of degraded performance of
open-wire (particularly the "window" type) lines.

Cheers,

Wes N7WS

My MFJ-259B says 1.5:1 at 3.56 Mhz -- the rig would load,
but the antenna
might not like it -- and I doubt if it would radiate well.

|If his family did come over on the slave ship, they probably owned it.

A couple of years ago my wife and I did some traveling through Iowa and Nebraska, where her grandparents grew up. We did a lot of visiting of small town libraries and historic centers where she did some research.

I was killing time waiting on her in some library when I casually picked up a volume titled (if I remember exactly) "Bonded Passengers to America."

This book documented the shipment of people (primarily from the British Isles) to America. The "cargo" consisted of either common criminals or other unwanted types who were usually sentenced to seven years of servitude. THE VERY SAME SHIPS that transported these people were also used to transport negro slaves from Africa. The only difference was that the survival rate for the Africans WAS HIGHER that the rate for the British.

In one case a "repeat offender" (a woman) who had done one seven-year trip and was again convicted in England, asked to be hanged rather than suffer another journey.

So, yes, a lot of Scots, Irish and English came here in chains and under worse conditions than did the African slaves.

Are you using a screwdriver antenna for your mobile ?? What brand?? How do you like it?? Any problems?? I'm looking to get one to install on a travel trailer, interested in your experiences.

Thanks, Bill

There is more to radiation than SWR. When a vertical monopole is more than
5/8 wavelengths long, it develops end-fire characteristics which sends the
RF mostly straight up. Since very little 146 MHz radiation is reflected
back down, virtually all the RF will be lost when using an HF monopole
on VHF. But I don't know anything about a Hustler 4BTV.

Well, while driving down the road, you tune the screwdriver using an
MFJ-259. Then disconnect the MFJ and connect your transceiver.
Just kidding. I choose an empty frequency, hit the antenna tune button,
and watch the SWR meter for a dip in reflected power.

I beleive it's getting the 5th harmonic of 29.2 MHz. My guess is the 10 meter trap also traps off very effectively anything above its desiged frequency.

So it's a vertical 5 half-wavelenghts long at 146 MHz. Why would it be no better than a "dummy load?" I'd think it would work about as well as a 1/4 wave groundplane....

I've run antennas on their third harmonic and they work OK (like a 40 meter dipole on 15). The ARRL Antenna book explains this in chapter 2, that antennas present low reactance at their resonant freq and odd multiples.

Thanks, Wes, for your thoughts.

I assume your samples were of a type which had a largish proportion of their lengths, perhaps 50%, with the pair of wires spanned by a plastic web. Perhaps more spacing material than the common-or-garden 450-ohm 'ladder line'. This would account for the large increase in loss relative to your control sample. It would also account for a reduction in velocity when wet.

I'm inclined to agree with you that water causes an increase in dielectric loss with a negligible effect on conductor loss. Although it should be remembered that a decrease in Zo (which actually occurs) does itself result in an increase in conductor loss even if the conductor resistance remains unchanged.

Conductor loss = 4.343 * (Conductor Resistance) / Zo decibels per unit length.

But what I really came back to say is - Dielectric loss is directly proportional to frequency. So if the additional loss due to rain occurs only in the dielectric then, from your measured values at 50 MHz, the losses at 1.9, 3.7 and 7 MHz, where such lines are mostly used, if not negligible are still small compared with the sum of other losses in the system.

From my own observations, in a torrential downpour (we do get them occasionally in the UK), with horizontal 300-ohm ribbon line (I have used spaced speaker cable), at 1.9 and 3.7 MHz, the first time it occurs it may be a little alarming to observe the SWR has crept up to 1.5:1. But since it can be corrected by a 5 or 10 percent change in L and C tuner settings there's nothing to worry about. After a time it can be ignored. Before the sun comes from behind the clouds the SWR returns to normal of its own volition.

I've never attached enough importance to the effects to attempt to quantify them. Nevertheless, it seems wet transmission lines can be an intriguing source of problems yet to be solved. ;o)

My main complaint about rain is rain-static noise. I once attempted to estimate the S-meter reading due to rain static for a precipitation rate of 1" per hour on an 80 dipole. But it would have been easier to read the S-meter and use instantaneous rain-gauges - if such things exist.

Regards, Reg G4FGQ

Source record: 149897

There are a couple of tuning mechanisms marketed for the screwdriver type antennas - one for about
$150 is a programable turns-counting device that requires a magnet and inductive pickup be installed
inside the antenna mast - it can then be set (after initially adjusting the screwdriver for best
match manually) to return to the previous setting at the push of a button and selection of the
appropriate memory setting on the memory-position knob.

A *far* more elegant approach, for about $50 more, is a TOTALLY automatic gadget, that requires NO
intrusion to the innards of the antenna itself, and automatically activates when the "tune" button
common to rigs like the IC-706 is pushed. It then senses the RF output frequency and current setting
of the antenna coil, and proceeds to tune the antenna to the best match TOTALLY AUTOMATICALLY!

THAT'S the one for MY money, when my mutual fund starts looking lots better than it does at present...

hey mark
the hard part about stacking a tri band beam is the spacing between the two yagis i suspect you would have to stack it with 20 meters in mind but as for the dissimilar yagis it would be sorta a problem with a good clean pattern but you should be able to find a couple of mosley ta33 or a pair of cushcraft A3's for somewhere under two hundred bucks but keep in mind the two antennas will need to be roughly a waveleght apart and on 20 meters thats a lot of mast to use
let me know what you find out and how it works

The histories of the first use of the terms 'electrical engineer', 'electronics engineer', and 'radio engineer' are interesting ones. Does anyone know the details?

I presume that the 'RE' designation was retired in the 50's, as it got confused with what we now refer to as the commercial enginers who run radio stations. I'd be interested in the details(or correction to my limited knowledge) though.

When did the IRE merge with the IEE(E)?

"Richard Clark" provided much detailed advice:

"Roy Lewallen" provide some more:

Are those guys 'over there' planning to gather a sufficient number of measurements of the EH Antenna's gain (for example) in both dimensions (azimuth and elevation) such that someone will be able to plug the numbers into MS-Excel and do some simple numerical "integration over the sphere" ?

I mean, if the average gain over the entire sphere integrates to about +2.709 dBi (to choose a random number), that would be a cause for celebration as the EH Antenna would certainly solve the world's energy 'problem' as well as being a half-decent antenna.

George

Sounds like a good idea. I was about to have a bracket made to bolt to 2
rafter ends, but when I got up there to measure it looks like they are
just separate 3' lengths of 2X6, toe nailed at the house end so I didn't
think they were strong enough to support anything. Do you think I missed
something about how my roof is constructed?

Steve:
Houses are built in all different kinds of configurations. If that is a hip roof, then that is certainly a possibility. If I could look at the house, I could tell all kinds of things, but without being there and able to tap on panels, etc., it is difficult to give any specific advice. If indeed those are rafter tails, and not full rafters, then you are correct that they are not very strong. And, from your comment, I gather that the ends of the rafter tails are open also, and there is no fascia board across the ends. Bummer. You need to get back to a structurally sound part of the house frame to be safe, and loose ends is a real problem. Not sure what else to suggest.

> There is more to radiation than SWR. When a vertical monopole is more than
> 5/8 wavelengths long, it develops end-fire characteristics which sends the
> RF mostly straight up.
==========
Cecil, just a minor correction.

For a height of 5/8-waves there are virtually no high angle lobes. At that height they are just about to start. A 5/8 wave vertical is the optimum height for maximum very low angle and groundwave radiation. Just the job for MF broadcasting (no high angle required to minimise fading at night) and real DX on the lower HF bands. The radiation pattern in the vertical plane is very broad as may be expected from from a single radiating element and so the one-hop ionospheric paths are very well catered for in all directions.

Even for a 3/4 wave vertical the higher angle lobes are just a couple of tiny rabbit's ears and nowhere near "straight up". Maximum radiation is still very low angle and along the horizontal.

The following should be in very small print:- Don't allow programs which predict field strengths at infinite distance to mislead you about true radiation patterns.

Vertical antennas don't begin to squirt power at high angles until height is 1 wavelength or more. In fact they never send anything straight up - there's always a null at 90 degrees. (Just like the Beverage always has a null in the direction of the wire).

My Dream of the ideal DX antenna for the lower HF bands is a 100-feet vertical above a ground system of 25 or 35 shallow-buried radials. That would be 3/4-wave on 40 metres, 0.4-waves on 80 metres, and 1/5-wave on 160 metres. It would still do very nicely on 30 and 20 metres for relatively short-haul one-hop QSOs. Sadly I shall have to continue dreaming.

Sweet dreams folks!

What is the biggest utility pole you have experienced setting? I plan on setting a 40 footer using a back hoe to dig a ditch eight foot deep and tapering out to nothing at about 18 feet or so. Plan on rolling the butt end into the 8 foot end then using the back hoe to push or pull the top end up. Of course will have to back fill the thing by hand. Any suggestions?

Unless feedline radiation--which is reputedly responsible
for much of the antenna's gain--is accounted for and eliminated in
the tests they won't have much validity. I think Roy suggested some
methods for measuring the common mode current on the coax.

This kind of "RF in the shack" problem is often caused by either
coupling from the antenna to the coax shield or unbalance in the antenna
itself, or both.

Try installing a choke-type balun in the coax somewhere before it comes
into the shack.

You may get advice to "ground" the rig, but running a ground wire may or
may not fix the problem. RF at ham frequencies is nearly impossible to
"ground" because the ground wire is an appreciable part of a wavelength
and has different impedances along it's length. This is not to say a
ground wire can not fix the problem, but it would be more luck than
science.

Be sure you run the coax straight down as soon as you can and as far as you can. If you run the coax horizontal to the antenna, it will pick up RF. GAP does not recommend a balun at the antenna. Get the coax away from the antenna before you go horizontal. That cured my problem.

Well, Mike, I can tell you the rugrats idea is completely out of the question:-)

I was thinking of a post too, but I'm surprised a 4x4 would be strong enough. There's someone in the area who installs lengths of surplus (wooden) utility poles as lot corner markers and jumbo fence/gate posts. Maybe I'll track them down and see what they can do for me.

What kind/size of mast did you use?

Reg may have forgotten to include a word or two in his statement. Broadcast stations limit their towers to 5/8-wavelength unless a phase-inversion is used beyond 5/8-wave because they "begin to squirt power at high angles". This is clearly shown in Fig. 23-25 (d) on page 887 of the 1955 edition from Terman.

Because the radiation is straight up. For instance, a 40m vertical monopole
has a take off angle of 62 degrees on 6m according to EZNEC.

> I've run antennas on their third harmonic and they work OK (like a 40 meter

The trusses themselves are manufactured 2X4, and yes, you are right, no fascia board. There's no plywood under the tiles except at the eaves, so it's a good question whether the plywood is holding up the rafter tails, or vice versa. The walls are 2x6 framed, which seems to be unusually robust in California, so I don't know why there's such a flimsy roof on it.

Sorry to digress from ham radio...

I used to erect fully assembled 70-foot radio towers with great frequency. These were hoisted at their center. A tower must be stiffened with an attached pole so it doesn`t kink.

The hoist for the tower was atop a pole slightly more than half the height of the tower. The hoisting pole is temporarily guyed.

The hoisting pole was erected using a Mack truck equipped with a power winch and an A-frame. It was snatched near its middle and a tag-line was used to verticalize the pole alongside the tower base.

The tower was then snatched near its middle and a tag-line was used to pull the tower bottom section over the tower base.

A similar method can be used to place the pole in a hole.

Best regards, Richard Harrison, KB5WZI

Yep, a 5/8WL antenna squirts considerable power out at a TOA around
sixty degrees. I hear that high angle radiation can play havoc
with fringe area reception of AM signals.

I missed the original post, but I would have to go with the
Screwdriver--that is, if you wish to
operate all bands. Assuming that is the case, you can buy some versions of
screwdrivers for
no more than it would cost to buy, either the Hustler mast and resonators,
or the Hamsticks.
The hamsticks, IMO, are the absolutely WORST choice although they work
fairly well up on
20 meters and above. The truth is, you just aren't going to get a "sooper"
signal with a pleasant,
skinny, unobtrusive mobile antenna. Because I know that a mobile antenna is
only about 18%
efficient (if that much) when referenced to a half wave dipole; after all,
you are taking 120+ feet
of antenna and squeezing it down into 9 feet or less--I tend to go for the
Biggest, Ugliest antenna I can get!

For single band work, I'd go for Henry Allen's Texas Bugcatcher. For
multi-band, it's the
screwdriver because it IS flexible and is extremely adaptable. By that, I
mean that, since the
antenna's environment is usually fluid and changing, the antenna can be
resonated to take into
account the changes--often with just a bump of the control switch, whereas,
the HI efficiency
(Q), fixed-tuned antenna cannot be changed. In spite of the higher
efficiency, the fixed tap antenna's performance degrades while the
screwdriver can correct for such. And again, by
the time you buy a Hustler fold-over and 7-8 resonators, you can buy a
screwdriver. Same thing with the hamsticks. They are simply more BANG for
the buck.

Cecil,

You may have meant it as a joke, but there are *some* of us who DO use the
MFJ 259 to tune the antenna via a 2-position coax switch. Actually, it
works pretty well as manual tuning
goes. I am saving my pennies for the AmCom controller, tho!

Rich, can you remember what fraction of total radiated power is diverted downwards, towards the horizon, by a phase inversion beyond 5/8-wave? A number please. It is of some importance in the present context.

Reg.

And how long would those 25 or 30 shallow-buried radials be?
(It's a serious question, I have a 60 ft tower up with 15 ft of mast above it mounting a HF triband and 2mete yagis for toploading that I'm thinking of shunt feeding).
Note that I don't wish to make the radials any longer than needed, even at cost of some small amount of efficiency.

With a vertical antenna height of 75 feet, assuming an average sort of soil
resistivity of 150 ohm-metres, 16 radials of length 50 feet will result in a
radiating efficiency of -

Effncy. Freq. Height
-------- -------- -------------
96% 10 MHz 0.76-waves

96% 7.1 MHz 0.54-waves

83% 3.75 MHz 0.29-waves

39% 1.9 MHz 0.143-waves

Data obtained using program ENDFEED.
The program also computes L and C values for a tuner at each frequency
located at base of antenna.

For efficiency with different number of radials of different lengths with
other values of soil conductivity use the program.

Regards, Reg, G4FGQ

You can actually minimize the feed line radiation by slipping over the coax a suitable number of ferrite toroids (i.e. by building an efficient common-mode choke); this is standard practice in Antenna works. I trust this will be done during the tests in Italy.

We are going to perform background noise tests next saturady, also one
of the scientists working there is part of our "group" so he probably
is aware about possible interference we might cause.

well, we might as well try something like this, I hope a standard tuner
can tune such a small antenna.

> I say this because you will be measuring the ground wave (line of

> fourth to a tenth with 20M.

So are you suggesting us to not use a well know reference antenna?
We are chosing the frequency in order to have the possibility to
use the half wave vertical monopole. We could test the antenna
even at 7 MHz, but in that case all we can erect is a quarter wave
groundplane with 30 to 40 full size radials lawn just over the ground.

yes, that makes sense and we probably end up doing that with a matched
short vertical and step attenuator.

> Set the attenuator to a value that is NOT 0dB insertion loss. Run a

> entirely ignored beyond the s9 = 50ï¿½V specification.

the scale has been calibrated with HP digital spectrum analyzer and
his signal generator (I forget the model number of the instrument),
the owner can tell the difference in dB between
each two S-steps. However the external step attenuator will be used.

> The technique here is akin to the balance of a bridge, but this

I fully understand what you mean. However you must consider that we
are just a group of amateur radio operators, with some professional
skills (everyone is at least engineer or physic researcher) and that
we are doing that on our spare time (read weekends) and also that
nobody will give us a cent for that (which isn't a problem after all,
but yet nobody between us believe this antenna is worth the effort
nonetheless we are going to test it carefully).

After some preliminar test we'll know how many measures we can reasonably take. I suggested Stefano to make some professional researchers and universitary labs test his antenna, but it seems they didn't take him seriously (I have doubts, but I don't know what he actually did).

I believe we can't find suitable instrumentation for this test in short periods of time.

> Now. as to terms employed (they DO NOT all mean the same thing):

[...] I skip this part in the quoting. Those terms are all very clear to me :-)

> You who are about to measure - we salute you.

To be honest I don't feel confortably enough in the part of the "measurer", Stefano chosed me (and I still don't know why, probably because we are in the same area). I would have preferred him to let

test his antenna by universitary researchers.

Thanks for all the suggestions.

I think the more practical thing to do for us is to move the receiving
station in different points (even some tenths of different points).
If the reference antenna and the EH will be placed in very (more than
half wavelenght) positions we'll try with swapped positions as well.

Well, if *I* were the inventor I would put my invention in the hands
of professional testers in the first place... But well, I didn't invent
anything in my life :-)

Yes, it's very important to reduce the feedline radiation to a very
small value, but it's also important to measure the common mode current
to verify that this has been successfully done. The measurement is easy
to make.

I think we can hardly fly over the antenna...
Sorry, we can just go around it at ground level.

I'll have to check my resources, but a wavelength apart would be a huge problem. I was thinking maybe 1/4 wave (~16') of spacing on 20 meters with a phasing line between them would do it. Phasing line length could be adjusted for each band. There are lots of cheap tri-banders out there, older ones are practically give aways. Friend of mine has an Old TH-4 (Guess it's 35 years old??) that still works fine with maintenance. Even if you only got say 2dB additional gain, 9dB total on 20 is in "Big Gun" territory.

Of course it's worth a try. Traps are parallel resonant (Hi-Z at resonance) at a frequency. They are not Low Pass filters. Low pass LC filters drop off at only 6 dB per octave which would be bad news as a trap. Hard to believe a trap designed for one frequency would by chance work as a trap at it's 5th harmonic. I think the trap will work more as a lossy series capacitor. The Z of the L will be sky high, and the capacitor Z will be very low. If anything you're working the 21st harmonic of the 40 meter vertical polluted with series capacitance. It will radiate something, but my money is on dummy load. Anyone ever try loading up a 40 meter dipole on 2? Tell us how it works!

As long as the SWR is low it will not hurt the radio. How well it will receive and transmitt is unknown. It might work well enough to do what you want or it might not get out across the street. Hook it up and see if you get the desired results.

I think that what Cecil was trying to say is that even though a person may achieve passing an extra class license test, there is no reason why a person cannot further their individual education. You cannot show me one Extra Class licensee, (regardless of year of license) that absolutely knows EVERYTHING about radio and electronics/electricity. There is so much to learn, that not one person could ever amass all the knowledge about the above subjects in two lifetimes. Plus there is the experimental factor. A licensee, regardless of license class, is encouraged (at least by me) to experiment, come up with something new. After all, had other not have done this, alot of the technology we appreciate now would have never been.

hey mark
its a neat idea a friend of mine wound up with 2 mosley ta33s and was thinking of doing the same thing but he has never gotten around to it
the nice thing about ham radio is not to much of it is cast in stone so all i can suggest is to try is and find out
my knowledge is limited to VHF stuff
all i can say is try to stick with 2 of the same antenna or atleast the same type of feed points you know both gamma matchs or both T matches
and they should be the same boom lenght or the patterns might be a bit weird

Good point about the matching and boom length.. seems the GetAroundToIt factor is the biggest problem with stuff like this!

I don't know what you were reading, but I didn't see this in the thread.

1) Amateur is not better than professional. It is merely an indicator that someone is probably genuinely interested in what he or she is doing. When someone takes such an interest in their work that they do it for (or have done it) for fun, you stand a pretty good chance of finding someone who takes pride in what they do. That's all.

2) Trial and error is often a maligned procedure. When environmental and system limits get less well known, sometimes this procedure is the only way out. You would be wise not to sneer at such methodology. At the same time, it's merely one tool in a very large kit of techniques engineers ought to know how to use.

3) A technician often knows something many engineers are woefully ignorant about: THE REAL WORLD PERFORMANCE. No, they're not "better" (whatever that means). They are important resources that you'd be wise not to ignore.

4) Soldering is a skill that is orthogonal to electrical engineering. Knowing what it is and how it's done is more important than being able to do it. Besides, these days it is done with machines...

5) I think most of us know folks from all walks of life who are really good at taking paper tests but haven't a clue about what they're doing. That's not to say that those who get low grades are good, merely that the grades you get in school don't correlate well with

real world performance.

The basic facts are these: Yes, you can have a person who is strictly an engineer who knows nothing of how technicians do their jobs. And as long as this person is designing a single use device which will be thrown away instead of being maintained, they'll do just fine.

However, an engineer who understands how technicians do their work has an edge over one who doesn't. They can design more maintainable products that technicians can work with and diagnose easier. It's a matter of knowing who your customers are.

Yes, you can still get a good engineer from someone who has no technical field experience. However, they'll have to work much harder at it than someone with a feel and a background of what the real world looks like.

That's been my experience as both a technician and as an engineer. They are both worthy positions. I feel that a good technician ought to be worth at least as much as a good engineer. However, few Pointy Haired Bosses understand what a good technician (or even a good engineer) can do for them. Without this knowledge, most PHBs fall back on the defective notion that a formal education somehow indicates intelligence and skill. Thus, technicians often get the short end of the stick.

That's what most of the people here are saying. I'm surprised you didn't seem to get it...

To a position of respect within the Amateur Radio Service. If an Extra chooses to rest on his laurels, i.e. contribute nothing of value after obtaining his ticket, he doesn't deserve respect. What is important is what one accomplishes *after* obtaining one's license. The same concept applies to a EE degree.

Jerry, you have given me an idea. It would be easy to use the voltage
driving the SWR meter inside the MFJ259 to remove the voltage from
the screwdriver motor - and presto, an autotuner function for a
screwdriver. Latch one of two relays with the up/down PB and
unlatch it when the SWR voltage inside the MFJ259 falls below
a certain value. That's about $10 worth of parts external to
the MFJ259.

I would've inserted the word 'necessarily' in "...the grades you get in
school don't <necessarily> correlate well with real world performance."

All in all, I'd rather have a pilot flying my jet who scored well on tests
and graduated from The Air Force Academy, a surgeon operating on me who
finished top of his class, president who scored well on tests and did his
homework, and a boss like Bill Gates with whom I could invest my confidence.

They are saying on-the-air they will be QRV for 8-10 days from their start date which was 28-Jan-2002. So based on that info they should be on-the-air till 05-Feb to as late as 07-Feb.

Weather conditions can change all that as well as equipment failures (generators,antennas) so it is advised to snag them as soon as one can.

Interesting, Roy, and thanks for filling in the blanks for us.

My account as I recalled it was correct with one important exception.

At my undergrad school, a chapter of the IRE was formed in 1950 and was
almost immediately merged with the existing chapter of the AIEE to form the
joint AIEE-IRE student chapter. That arrangement continued until my
graduation in the mid-50's.

So, I was confusing that strictly local situation with a national merging
of the two organizations which did not take place, per your
mild-slap-on-the-wrist comment, until 1963.

I had been out of grad school for several years by 1963 and was not active
in either professional society at the time of their merger. For those who
know of the work climate at Texas Instruments in the early 60's, there was
precious little time and energy left over for professional society activity
in those days.

Dick, Ham Radio licenses are not scouting merit badges. Neither are
degrees, certifications, licenses, membership, citizenship or anything
of the sort. They are a means to an end.

I know that some out there like to collect merit badges all through
their life until they're certified and certifiable. This is the
Scouting mentality run amok. I have a serious problem with anyone who
seeks certification for the sake of certification. They may be legal
to operate the sorts of things they're certified for; however they
often don't care enough to learn any more than what it takes to stay
certified.

I have little patience for folks who have alphabet soup credentials
and very little real experience. It's not about the certification one
has, it's what one does with it that matters.

Can anyone help.
I have checked my radio using a dummy load
and the output is 125watts.
when using an atu my radio output is only 60watts swr 1:1
when going straight out to antenna radio out put is 125watts swr 1:1.5.
I have tried 2 atu's and the result is the same
anyone have any suggestions.

Wow, I was just being silly, I don't really consider myself to be in a minority group.
(Other than Amateur Radio that is :) I'll have to go to the local library and see
if I can find that book, sounds interesting.

I notice in a Consumer Reports guide to all the latest vehicles, the magazine does not recommend buying a Chevy Surburban or Silverado -- reliability problems. They also recommend against buying the GMC versions of those vehicles; same reliability problems.

>>
>> Anyway, you might look into using a post for support. It might
>> work for you.
>>
>> Mike

I put my mast, a 3" diameter pipe, 1/4"+ wall, 21' long + a 6'X2" 1/4" wall pipe next to my garage. Now granted this Wisconsin house/roof/soffit assembly is probably stronger that a CA version, but...
I went to the scrap yards and found all the pieces I needed for about $20.00. I picked up the mast pipes, four sections of 1 1/2" X 1/4" thick angle and a water pipe-free from a local plumbing shop-used but like new, to drive into the ground to anchor the mast to/over.

I have facia boards so I used 1"X4" to space the angle down. This eliminated notching the facia. Next I built a rectangle out of the angle that went from tight to the wall on one side to 3" beyond the facia. This was bolted together at the angle corner overlaps. This was then mounted to the soffit by screwing up thru holes drilled into the angle/spacer and then screwed into the 2X6's. I then drilled thru the angle and the wall into the garage and put in threaded rod to a 2X6 board that crosses 4 of the studs in the wall. I drilled 2 holes at 90 degrees to each other through the pipe at the bottom and put an anchor bolt thru the mast and the pipe that I had driven into the ground (Water pipe, drive at least 8' into the ground). This holds the mast down, supports the mast and eliminates side movement so the soffit is nothing more than a minor alignment bracket. I then drilled 2 holes in the angle that runs parallel to and outside the facia to mount my u-bolt. To join the 2 mast pieces I overlapped the masts by about 18" and drilled 2 holes thru at 90 degree angles, I angled the holes downward a bit to create resistance to movement. I then inserted some steel scrap that I had around to keep the outer pipe from collapsing when I tightened the bolts.

Now I have a KT34 mounted on a rotor at the top of the mast pipes. On top of the rotor I have an 8'X2' dia., thick wall alum mast. At the top of this is a 10 element switchable polarization 2 meter beam. I live on top of one of the highest hills in my area, yes it sways a bit but it has not bent or come down. I also did the same with a fringe tv ant. The tv antenna is on top of the same type 3' pipe but from there it extends another 12' to where the ant is mounted. This is mounted at the other end of the house and is not through bolted. Less

wind load.

Both are doing fine after 2 years. I hope this helps.

I know that this mast set up, the KT34, would not work very long
without the thru bolting,but if you have a garage, attached or nearby,
it could work for you too.
Dan

I've rambled enough, back to the rocking chair. ZZZZZZZZZ

Crap like this is why I never bothered to get a ham ticket. I built one of the first 2 meter FM repeaters in southwest Ohio in the 60's, helped my high school start a ham radio club, raised the money to buy the equipment, and got permission to put up all the antennas on school property. Then i listened to the boring, boastful morons who bragged about their license, their new tower, and that their station cost more than someone else, and decided I wanted nothing to do with it. I went into broadcast, and manufacturing, working with state of the art microwave equipment that is used all over the world. I enjoyed building and repairing the equipment more than spending hours of listening to crap.

I have watched as the technical level of hams continued to drop. I had one tell me at a hamfest that the day he had to solder a plug on a cable he would sell all his equipment. I suggested that everyone would appreciate it more if he didn't wait. Its sad that I get phone calls from hams who can't read the manual for their latest chinese box to wire a microphone, or who don't understand the first thing about the proper way to install an antenna at their home, or in a vehicle. I have known a few hams who were very good techs, or engineers, but every one of them have become inactive, because they got tired of all the idiots on the airwaves. I have worked with a few engineers who were excellent designers in RF, and they had all been hams, and several kept a copy of the ARRL handbook in their office to remind them where they started

their career. I never cared for morse code, so HF didn't interest me, and 2 Meter quickly became a CB band with a phone patch. Welcome to ham radio, any class, but these days, there aren't very many hams who care to learn electronics, or try to keep up to date. Of course, having worked at sites with 5 MW ERP, and 1700 foot towers, you get to where you don't care about anything but signal quality, and zero downtime. I miss the days I could call a ham or two and discuss electronics. I used to love to design HF receivers, but I can't put up a decent antenna where I live. So, I'll probably go back to working as TV engineer. At least the new HDTV systems will hold my interest, hopefully till i retire in 14 years.

The antenna's first trap, about 9' up is labelled 10 meters, above that is
15 and above that is 20.

I see what you mean now. The 10 meter trap is a high Z at 10 meters, so it's
wrong to assume that it's also a high z at 5x 10 meters (146 MHz).

However, I couldn't resist the experiment, so I made a 10 meter 1/4 wave
groundplane and put it in the center of my antenna lab (OK, my garage) and
also a 2 meter groundplane. I a/b tested them and they were roughly
comperable. Both presented nice looking loads to my radio (and to the
MFJ-259B)

Slide Rule, eh... I wonder what ever happened to my great Hemi bamboo log-log only cost me, $35 complete with leather case. No need to upgrade with new version numbers every other year either! Better times?

I was at an IEEE Section meeting a good while ago, where there was a heated discussion, one that emerges from time to time, regarding a desire on the part of some elements within the IEEE Computer Society to separate from the IEEE. Of course there were, and still are, two sides of the aisle on this issue, and the existence of the venerable ACM is often thrown out as an alternative, or refuge, for those who maybe wanted a separate organization with a little more scientific/software bent and less Engineering.

Somewhere in the midst of this heated discussion, some wag offered the following comment: "Back then we didn't have "Slide Rule Scientists" why do we now need "Computer Scientists"... this was followed by a lot of laughter and the tone of the meeting degenerated thereafter...

2031. Re: Stacking Tri-Banders

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-29 17:29:32 UTC
From: Patrick Croft <mai@iquest.net>
Message-ID: <3C56DBFC.6A4FD214@iquest.net>
Source record: 149818

Guys-
do a little searching and planning - Dean Straw and K1VR(?) wrote a
excellent paper on stacking tribanders in QST - era 1995. Several sites
online area also full of details. To 'try it and see' is a major
mistake - sticking up antennas even as small as A3's gets old when you
have to change them a ozen times. Software modeling will save you the
pain of not planning.

FYI - the rule of thumb is 3/4 wave spacing. But that only works for
certain TA's.

Visit Array Solutions website - Jay is well versed in stacking and can
offer concrete advise for various yagi's.

Bests,

Patrick

Reg wrote:
"---can you remember what fraction of total power is diverted downwards, towards the horizon, by a phase inversion beyond 5/8-wave?"

Depends on how much more antenna you stack above the 5/8-wave section. The more common configuration is a phase reversal at the 1/2-wave point so that the added length is in phase with all of the first section of the antenna. Seems to be a problem for modeling.

The most common broadcast application has probably been stacking two 1/2-waves, which is a full wave center-fed. This is called a Franklin. Two 5/8-waves have also been stacked for the truly power hungry.

These arrays are also called "collinears". The 19th edition of the ARRL Antenna Book shows the configuration on page 8-2 in fig. 2(B).

I`ll borrow the words of John E. Cunningham in "The Complete Broadcast Handbook". "---it is apparent that, for the greatest primary service area with a given radiated power, we should maximize the radiation along the surface of the earth and minimize the radiation at angles above the horizon. One approach is to use a tower that is nearly 1/2 wavelength high. If its height is increased beyond this, a high-angle lobe will form that can cause skywave interference and reduce the distance to the fading wall.

As noted earlier, the vertical-radiation pattern of an antenna is related to the current distribution along the tower. In Fig. 6-16 we see that when a tower is greater than 180 degrees (1/2-wave), there is a phase reversal of the current. This means that current is flowing on the tower in two directions at the same time. This is responsible for the high-angle lobe that is found in the vertical-radiation pattern in towers that are taller than 180 degrees. If we could find a way to avoid the phase reversal in a tall tower, we could increase the field intensity along the surface of the earth without creating a high-angle lobe in the pattern. This can be done, and many different types of antennas have been designed for the purpose.

The simplest antenna of this type is the so-called Franklin antenna or Franklin array, shown in Fig. 6-17. Here we have two 180 degree towers, one mounted on top of the other. This arrangement does not act like a 360 degree tower because of the way signals are fed to it. The feed system is designed so that the currents in the two 180 degree sections are in phase----".

Cunningham did a far better job of explaining the Franklin than I could, and I won`t add anything to it although there is a lot more to the

subject. You can find more in literature on the colinear or collinear array.

Best regards, Richard Harrison, KB5WZI

I seriously doubt anyone sits the RAE without the intention of operating a
radio, it is a pretty specific test, (especially the licensing conditions)
and unless one takes an interest in amateur radio I think learning enough to
pass would be very difficult. However the certificates are simply an
indication that you can set up, maintain and operate a radio without causing
interference to others. Michael A Terrel made a very valid point and I left
AR for similar reasons to his. There are at one end the snobby intellectuals
who didn't like to speak to class B operators, newbies or anyone they didn't
know, and at the other end the black box brigade who used 2 and 70 like CB
channels and wouldn't know a PA from a PLL. There are some very decent
people in AR but the bad ones are the loudest, unfortunately. At the end of
the day anyone who gets their AR pass purely as a ticket to financial gain
has kind of missed the point of it all.

> -Bill

Not at all. Its just that over all, ham radio isn't what it was. At one time a ham was knowledgeable about his equipment, and most took pride in the quality of their work, and how they behaved on air. Its rare to find more than a handful of hams these days that can repair their equipment, unless they are old timers, still running a tube rig. I realize that modern equipment is complex, but most of it is overly complex for the job. I'll admit the telemetry equipment I worked on was quite complex, but i also realize it was used by people who had little idea of how to make it do what they wanted it to. Up to 12 IF bandwidths and 12 Video bandwidths confuse most users.

A radio to talk to someone on a single, or a couple bands should be built to be repaired, even if only by being able to run diagnostics and exchange a bad board from a repair center. My point was that most hams these days do not measure up to technical standards like they did in the past. Also, I don't mind helping the local hams, if asked. What i do mind is when one arrives, demanding help with something he should be able to do. Solder work is simple in most cases. I understand doing it with vision problems My eyesight is poor. 20/200 & 20/400. But I compensate by using better tools. I have to do most of my solder work under a high power stereo inspection microscope. That doesn't stop me from working on 288 pin surface mount parts. I am self taught, and I continue to learn, almost every day.

There is nothing wrong with being a ham, unless you have no desire to learn. It really should be the end, rather a tool to an end. I feel that you should keep learning, all your life. If you reach a point where you don't exercise your mind, you'll start to lose the ability to learn. I'll be 50 in a few months, and I do not have an EE to my name, but I have spent a lot of time fixing design problems, after i show the

engineer that I know what I'm talking about, and that all i want is Stable, buildable piece of equipment. I hope you can do most, or al of your own work. it give s satisfaction to attack a piece of dead equipment and make it work, or start with a blank page and build something from scratch.

Also, its not just hams who are letting their skills fall behind. A lot of ET's and some EE's are so far out of date that they are nearly useless, because they haven't done anything to learn new skills.

Take care, and God bless.
Michael A. Terrell

if you say straight out the antenna it is 1.1 why in the world would you
even consider putting an atu in line. they will cut your power back.
The best thing to do is to have ALL your antennas at resonate for the
band you wish to talk on. then you don't have to use one.

The word is redundant. Correlations can be poor as well as good. I'm
saying that you can sit and learn theory all day long, you won't know
who can do what until they're put to the test and faced with a
practical application.

>All in all, I'd rather have a pilot flying my jet who scored well on tests
>and graduated from The Air Force Academy, a surgeon operating on me who
>finished top of his class, president who scored well on tests and did his
>homework, and a boss like Bill Gates with whom I could invest my confidence.

Then you're looking for the certificate, not the performance. Bill
Gates didn't graduate if what I've read is true. Military pilots
don't make good captains of civilian airliners, (Cockpit Resource
Management isn't something they teach much at the Air Force Academy).
And I'd rather have a surgeon who is relaxed, done the operation many
times before, and has had a good night's rest.

It seems to me you're falling in to exactly the same trap that I
outlined before. If you know nothing else, go for the certificate.
If you're looking for someone to do the job right, look beyond it.

My, what rosy colored glasses you're wearing. It's amazing how cool
the hobby looks when you're young and don't know half of what's going
on. Why not re-read QST editorials and other such magazines going all
the way back to the early parts of the last century. That will set
you straight.

Hams have ALWAYS been sneered at. Their technical abilities have
always been sub par. The reason is that ham licenses are licenses to
learn. The ham radio spectrum is reserved for people to play with
the technology. If it didn't exist, it would have to be invented all
over again to accommodate the demand.

And yes, when you're fooling around and having fun, you're not going
to sound professional. Why should hams be any different?

I don't get on the air much, but I do design stuff and occasionally
test it on the air. Having lots of "Rotten QRM" to work with helps me
at improving on existing designs...

>I realize that modern equipment is complex, but most of it is overly

As should we all. The only question is to learn about what?
Antennas? Operating practices? Propagation? Radio repair? Radio
design?

Yes, that could be a problem, especially losing power to the tuner
that the EH has accepted (and presumably not lost to its matching
elements).

No. Don't go changing the frequency now. What I was suggesting was
the comparison to the EH be made by a simpler variant rather than the
larger, more problematic Standard (be it 0.25, 0.5, or 0.625
wavelength). The logic is that if the EH is no better than a well
documented small antenna, it could not be better than the Standard.

You might reflect that if you anticipate trouble with matching the
transmitter to a small antenna, then matching to the receive antenna
will be no easier.

Hi Francesco,

You will feel much more comfortable if you build the test plan before you get to the site. The testing itself, with the observation of all the comments both Roy and I have made, will proceed quite easily. Most of the work is in the handling of the results. With such in mind, it is better to have a lot of data rather than a little. The test plan will reveal how much you have available to interpret.

As for the full size Standard Antenna, or a much smaller one, there are several considerations. For one, how is the debate framed? The EH proponents will claim superior or equal performance to the Standard size antenna, but do they all agree what size that is?

Testing should anticipate future disputes, or should short-circuit them. The proponents of the EH also claim "mysterious" characteristics somewhat in the mold of the psuedo-science of fractal electro-magnetics (fractal-electro-magic). They also deny correlation to already well studied small antennas. If you can draw a correlation by comparing to a known small radiator, you close that avenue of specious defense. This would also eliminate the appeal to such nonsense. The logic goes, if they cannot do better than a simpler small antenna (same size, same elevation) why bother? The extension of this logic is that if they cannot perform better than a known poor radiator, there is no reason to presume they will do better with a larger one (the poor, known, antenna already establishes that fact).

Myself, I am not terribly concerned about induced or conducted spurious currents in adjacent structures. The swap of antennas at the same drive point should exhibit similar characteristics (for small antennas of equal size/elevation). However, I am fully supportive of taking of that data.

This is certainly not the end of the topic. I would suggest, again, build a more complete test grid and publish it here for comment. The plan should emphasize the data to be taken, and not necessarily the means of obtaining it (we've done that largely).

i would recommend checking with the local utility company, they are very experienced in such things and have the right equipment.

If you do ending up digging a ditch like that to lever it up, and are lucky enough to get it vertical, be very sure that when you backfill that you compact the earth very well, and i don't mean by foot, rent a real tamper and use it every 6" or so. If you don't you will have a weak side on the hole that is holding up the pole.

That's an interesting perspective. I've found that employers of engineers never, ever ask how well one did in school unless hiring a new graduate with no other experience. Instead, they're intensely interested, as they should be, in what the candidate has accomplished in his career, as the best indicator of what he's likely to do in the future. I'd rather have my heart transplant done by a surgeon who had done 500 successful heart transplants than one who was at the top of his class but had done only a few which he flubbed. Likewise for pilots. When the visibility is bad and the landing gear flaky(*), I'd much rather have a pilot that lived through 20 years of flying bush planes in Alaska than some fellow who got the best grades in Military History, English Literature, and Differential Equations at Colorado Springs. But you make your choices and I make mine.

Bill Gates, you know, is a college dropout. I have no idea how well he did while he was in school, but suspect that his extracurricular activities interfered with studying.

Roy Lewallen, W7EL

(*)True story: I'd been dozing since shortly after taking off from the Indian village of Hughes, Alaska. The Fairchild F-27, a two-engine overhead wing turboprop, had only a half dozen or so passengers, just me and the other members of the crew that had been overhauling the radar at the remote DEW Line site, and a load of mail. As I came out of my sleepy haze, I saw that we were circling a remote FAA station that was a frequent stopping point in that part of Alaska. It was getting dark. A few rows in front of me, there was a fellow shining a flashlight out the window at the landing gear. He was yelling to the pilot through the open cockpit door. "Well, she looks like she's locked, but she don't say she's locked." "What the hell," came the response, "We gotta get 'er down sooner or later."

And that's just one of the stories.

Don, All ATUs have losses. Some of your input power is converted to heat, mostly in the inductors. You are listing a -3dB loss which seems high. This is caused by high circulating currents inside the ATU.

Now a VSWR of 1.5 to 1 is a voltage reflection coefficient of 0.2, or a power loss of 4% or -0.18dB. If you really have a 1.5 to 1 VSWR forget the tuner!!

> practical application.

Agreed. But that's not exactly what you said in the original version. You are now saying one can sit all day long learning theory and not understand practical applications. That's different than saying grades don't correlate well with real world performance. Unless you have some scientific evidence that demonstrates grades have no correlation with real world performance I'm afraid you're just propagating a popular american myth.

How many kids use the stupid excuse: 'But Einstein was a poor student' and look what he did!', not realizing Einstein spent his youth in special academies and European gymnasiums because he, in fact, was a good student. We seem to want to believe poor grades, bad academic performance, and lack of theoretical knowledge is a good thing. I suspect that this is an american concept; we don't want anyone to 'feel' bad for not making the grade.

You previously said:

"5) I think most of us know folks from all walks of life who are really good at taking paper tests but haven't a clue about what they're doing. That's not to say that those who get low grades are good, merely that the grades you get in school don't correlate well with real world performance.

I know plenty who have done well in school and enjoyed real world 'success', whatever that is. As far as studying for the test in order to make the grade, I think tests can indeed provide a focal point. I was a liberal arts major. I never really knew much about electronics nor do I even know any physics buffs or electronics people. What I know is self-taught. Had it not been for the Ham license upgrades, and the practice tests, I still wouldn't have a clue. Heck, without a test I wouldn't even know where to begin to study. I do tinker, but, I always know how long to cut a dipole and a loop because I learned the formulas in order to pass the test. What we accept as common knowledge, common sense, is for some theoretical.

I think of tests as goals because I know that while I reach for a goal I'm also learning the important stuff along the way.

Hi,
When a set with a ferrite rod aerial is used or a set with a Frame aerial, interference from electrical items and TV is minimal. Any set requiring a wire aerial, around the picture rail for example, gives terrible signal to interference ratio in the same room. What gives? I should have thought that the "RATIO" would be the same so only signal to noise difference would be an issue.

Is it intrinsically "quieter" to capture the magnetic component of the wave?

As others have recommended, check with whomever sets the poles for the local telephone or power company. Often it's an independent contractor. I seem to recall that 8' is considerably too deep for a 40 foot pole. The pros can drill the hole just a bit larger than the pole, and you'll end up with a much more solid installation. It's been a long time, but I remember that the guys who installed mine even put plastic down on the grass to catch the dirt that the drill through up. When they had the pole set, they backfilled and hauled the excess dirt away.

Assuming that you have more than enough signal strength, you can "match" the receive antenna to the attenuator and/or receiver simply by inserting a fixed attenuator in series with the antenna. Anything connected to either side of the attenuator will see very nearly 50 ohms. You can't, of course, use this simple method at the transmitter, since you'll be comparing different antennas having different impedances. (In theory, you could, but then the power to the different antennas would be different. And this could be measured and accounted for, but it's wisest to keep the power applied to the antenna, and everything else you possibly can, constant for all the measurements.)

I've got a simple question about a "shorty forty" antenna I've built (details at http://www.flashwebhost.com/circuit/shortant.php). Now, I've got the coax (RG-58) coming off the antenna down to my shack. When I just connect the center conductor to the receiver (for now), everything works great. But when I attach the coax to the BNC connector, and then to the receiver, the signal disappears.

Where do you connect the shield/braid of a dipole? To ground?

Message-ID: <ryH58.4167$0V6.149@nwrddc02.gnilink.net>
Source record: 149747

I do recall that a loop (H field) antenna will pick up less near field interference compared to a rod or wire (E -field) antenna.

This is because the H field decays more rapidly in the near field compared to the E field. So if you are near the interference source, the H field antenna will work better

I cannot find a reference to this. Perhaps someone else can.

Also the loop antenna is directional and can be aimed to pick up the desired signal and reject the interference.

Let me put the question to you this way:

Can you tell if a woman is beautiful based upon only a single cross section
?

Often, the antenna 'glossy brochures' will have both elevation and azimuth
pattern data (typically a single slice each). Even with such a limited data
set, it can be interesting to plug the numbers into Excel.

Hi Richard,

I actually refer to Isbell and DuHamel in the original post.

It is a nice piece (that you refer to) but I am having fun with the
'pre-history'---as it were.

Nice to hear from you.

Hi Richard,

This is one of the singlemost absurd comparisons I have ever seen you draw (you hit a hot button). You would have failed utterly and abysmally if you had chosen to compare Lee to Grant on the same basis!

These two men exhibited the one compelling virtue that is a required, according to MacArthur:
"From the Far East I send you one single thought, one sole idea - written in red on every beachhead from Australia to Tokyo - "There is no substitute for victory!""

From Schofield's Definition of Discipline:
"...He who feels the respect which is due to others cannot fail to inspire in them regard for himself, while he who feels, and hence manifests, disrespect toward others, especially his inferiors, cannot fail to inspire hatred against himself."

Both quotes from "Bugle Notes," published by the Corps of Cadets, 1958. This book is mandatory reading, to the point of instant recall, for ALL cadets.

BOTH MacArthur AND Custer exhibited considerable arrogance. BOTH MacArthur AND Custer saw their fortunes decline after their initiation to war. BOTH MacArthur AND Custer lost major engagements. It is only through the accident of history that Custer died and MacArthur escaped by PT Boat (commemorated in John Ford's classic war saga "They Were Expendable"). There is absolutely no correlative in GPA, class ranking or any allusion to academia that separated their brush with

death and in their willingness to step up and take the risk personally.

If MacArthur had died during his escape, we would have celebrated his massacre by the Japanese (instead of the indians). However, his career would have been no more, nor less accomplished than Custer's. Face it, he was in the Philippines because his career was washed out - just like Custer's posting to the wilderness. Any other interpretation of their careers to these points is misty eyed sentimentalism.

Both MacArthur and Custer subscribed wholly to the West Point motto: "Duty, Honor, Country"

Few realize that the hallmark of West Point went far beyond the battlefield. The officers of West Point were the first American Engineers of note - they built the infrastructure of the 19th century that turned the Louisiana purchase into a productive part of the growing nation.

West Point is the bedrock Engineering school of every road, canal, bridge and railroad found east of the Mississippi. No other school in the world could compare in the remarkable talent that graduated to form "The Long Gray Line." Those, who feel dunned by this attitude and wish to challenge it should study their history, much less the admissions of those other schools to this very fact. The bottom of any class (the "goat") at West Point would've been first at another institution.

Our Civil War was considered the first modern War and was studied by every military attachï¿½ from Europe as it was being conducted. Later, from our junior service the Navy, Alfred Thayer Mahan's "The Influence of Sea Power upon History" was considered by European attachï¿½s as a masterpiece of history equal to Jomini and Clausewitz and required reading for the emerging issues that lead to World War One.

As a sidebar, I would point out that the single greatest failure of an Engineering education is to be educated only as an Engineer. I would also point out that Engineers are notorious for being poorly tutored in the classics of humanities and arts - by the students' choice, and the collusion of schools. This is/was not an option in the curriculum at the Point.

Roy Lewallen wrote:
"I`ve found that empoyers of engineers never,ever ask how well one did in school unless hiring a new graduate with no other experience."

Depends on the employment climate. But, I agree with Roy on this point, in general. Why question an academic record if a more recent work record exists. It`s usually more indicative of what can be expected from a new hire.

I`d intended withdrawing from this discussion because I think this group wants to believe that academic acvhievement is of secondary importance. My resolve didn`t last.

Acadremic achievement is not only a fair indicator of continuing academic achievement but in a work situation which requires the same traits, brains and a work ethic, it is an indicator of performance on the job.

Employers of new graduating engineers pick the schools that will be used for recruiting. Recruiters can pick from those who came to college on the basis of merit scholarships and those who won honors in college. It`s a matter of record. Some graduates will get invitations from many interviewers and some will get few if any.

Academic achievement counts!

Best regards, Richard Harrison, KB5WZI

If your going to use the pipe you might try using a fence post driver.
Basically its a bigger pipe with a end cap and you slam it up and down on
the pipe or rod your driving in. It would help.

2074. G5RV to Icom 746

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-30 03:21:23 UTC
From: Tom Nelson <nelsonca@stormnet.com>
Message-ID: <3C5766B3.2FF18BC8@stormnet.com>
Source record: 149761

The manual of my new 746 explicitly advises against connecting anything but coax to the output. Is there a G5RV that I can build/buy to skirt this problem? I'm thinking there must be a coax balun combination that I could put ahead of the ladder line to make things work. I would prefer to use ladder line to keep the initial SWR as low as possible since the built-in tuner of the 746 does not seem to offer much latitude.

The built-in tuner of the 746 does not tune my existing antennas to 40 Meters like my Kenwood AT-250 does. It WILL tune the same antennas to 10 Meters where the AT-250 would not! I'm wondering if anyone has had success using a multiband antenna like the G5RV with the 746?

Thanks in advance
Tom

Doesn't the G5RV have about 80ft of coax? Your 746 should be able to
tune 80m, 40m, 20m, and 12m using a standard G5RV. Also 15m if you're
lucky. There should be a 1:1 choke balun between the coax and twinlead
on a G5RV.

I fit this description as a student. All I cared about was giving the teacher or professor the answer he/she wanted. I didn't care about how well I learned the material. This pattern worked fine in K-12 (I was salutatorian, National Merit Finalist, and Advanced Placement Scholar with Honor), but it broke down in college. Unfortunately, it seems that today's students are even more deeply entrenched in the Academic Performance Cult than I ever was.

The U-turn in my attitude towards electrical engineering concepts illustrates the difference between know-how and studying to pass a class. I am living proof that you don't need to understand the material to pass a class - you just need to be skilled at regurgitating the "right" answer (or something resembling it) on homework and test papers. Only recently have I begun to truly grasp SWR, antenna efficiency, antenna patterns, matching networks, and filter circuits. HAM RADIO MADE THE DIFFERENCE.

Dave -

I think you got some bum advice there. Copper is a very reactive metal and
will not last any longer than the steel clad rods you used before, maybe less.
I don't know what would be better but you might try aluminum wire buried in the
ground like a radial.

Cons of prior ham radio experience for EEs:
1. Some of you have said that prior ham radio experience could make an EE cocky, and this would be an impediment for an EE student.
2. Some of you also mentioned that not all hams are interested in the EE principles. I was like this for about my first 3-4 years as a ham. Being a weather weenie and discovering SKYWARN is what drew me into ham radio, and I considered myself a SKYWARN ham and social ham but not a technical ham.
3. One of you mentioned that several hams you knew dropped out of school because they could earn good money as broadcast engineers.
4. Roy mentioned that his professors didn't know the practical world and that he found this to be an impediment in the academic world.
5. Richard Harrison said that the EE curriculum left little time for ham radio. Mac tells of one ham who was an enthusiastic participant in the lunchtime seminars flunked out (but somehow managed to pull himself back together elsewhere).

Pros:
1. On the flip side, Roy easily found a job in spite of a GPA of only 2.01. Roy reminds me of Einstein and Bill Gates - he had more productive things to do than the extra studying required to get a B or A average instead of a C - like designing instrumentation for the company that would later employ him after graduation. Roy: Would all this have been possible without ham radio? (On the 4.0 GPA scale, I graduated with a GPA of 3.13. I would have killed to be more like Roy, even with the MUCH lower GPA.)
2. In Mac's experience, most of the best engineers and faculty members in his college days were hams. Whether their EE curiosity drew them into ham radio or ham radio aroused their EE curiosity, the curiosity motivated them to learn the material.

I am still convinced that prior experience in ham radio is usually a substantial advantage to an EE or an EE student.

I can only speculate, but I'll bet that any good study would show that EE students and EEs tend to be better performers than their nonham counterparts. Of course, the correlation wouldn't be perfect, and the factors I summarized in the list of cons would be good reason for this. It would, however, be interesting to see just how strong the correlation would be. (Admittedly, things like GPA and salary don't tell the whole story on how successful one is.) I should ask the ARRL to do a study on this.

"Ham Radio made the difference."

That is great! The more you know, the more associations you can make with new knoweledge. Associations assist recording, retention, and recall. Repetition is a big help too. All memory is a memory process, even mathematics.

It may be dangerous to your grade point average to spend too much time on subjects on which you won`t be graded unless they are closely related to to your test subjects.

Part of the equation that's not going to reveal itself in the discussion here is the ham+ee+internet fan combination.
I know lots of technically minded hams or EEs that have no use for Usenet and Usenet nurds that have no use for hamming, and the combinations so forth.
After all the culling, there's few individuals here to present the argument...but that doesn't imply that its wrong.
EE curriculum and hamming are entirely different disciplines. The only common thread is the enthusiasm to immerse oneself in the interest. The same may apply to ee's (or hams) who are also model-railroad buffs.

That's odd, I've owned a 2000 model Sierra 1500 for the past year and a half,
32,000 miles worth, and it's far and away the most reliable - and in every way the
best vehicle - I've ever owned.
I won't even drive the Ford car anymore- it sat til the battery went down, and I
used to be a Ford man.

Reality check! Millions of copper-clad ground rods, millions of radials buried in the earth, copper roofs over countless ancient buildings in the world, millions of copper radiators, millions of buried copper water pipes, would all these be in place if copper were "a very reactive metal"?

Jason:

It seem from the comments on this thread that many participants do not really understand what it means to be an Engineer.

Practical experience, theory, and passing tests go hand in hand in the creation of any Professional. Medicine, Law, Engineering, etc... all require both rigorous practical experience, and some academic training... Folks who aspire only to be bookish nerds need not apply! Ya gotta produce as well as pass tests! I'm sorry, but to be good, "ya gotta have it all"! If not, you are simply not within the classification of "Professional".

Such statements alone certainly do not protect us from "false prophets". And so... when presented with an individual claiming to be an Engineer, I say... caveat emptor. Since today you can get a "Microsoft Engineer" certificate with a few hundred dollars and a few days memorizing a few hundred multiple choice questions.

Would you like the gal doing your triple bypass operation to have got her medical accreditation by that method? The same is true of the ham license, except you don't have to spend as much to pass the multiple choice exam. Many years ago, in many parts of the world, it used to be the case that you could not obtain a higher level ham ticket wihout first proving that you have built, tested and operated radio equpment over at least a certain specified time period. I wonder today... just as we all seem to agree that the overall requirements to become a ham have been watered down over the years, I am not saying that this was/is a bad thing, since ham radio is amateur not professional, but do you suppose the same thing is happening to Engineering?

Paraphrasing Marvin Minsky, one of the great leading thinkers on intellgence, "An ounce of perspective is worth 50 points on the next examination". More to the point, we could do no better than think about the famous quote from Rudyard Kipling who wrote the "Oath of an Engineer", that to become an Engineer, one must first have experienced, "the perversity of inaminate objects". Engineers are the Sons of Martha, not of Mary!

Despite what many say, and some believe, a graduate of a four year engineering school, is *NOT* an engineer. Myself, I was a technician, trained in the military service for four years, before I attended University, and so I approached academic Engineering with some awe and trepeditation. Later, I recall saying to myself when I graduated, "Is that all there is?" I simply couldn't believe that "they" would let me out of that engineering school with such little knowledge and so ill-prepared. What??? Heck... I wasn't an Engineer yet!

In many jurisdictions the role of Professional Engineering is "policed" as is Medicine and Law by professional societies. It is often strictly forbidden in some parts of the world and in some fields of practice, to call oneself an Engineer until one has at least served an "apprenticeship" as a graduate engineer in training, having demonstrated at least several years of working in the creation of practical designs...and having passed the various criterion set forth by an association of practicing Engineers, not of academics! This universally requires, as Kipling would say, "practical experience with perverse inaminate objects".

To be an Engineer is to be a truly well rounded individual.

Not only should an Engineer be an extremely practical person, but she should also be skilled in academic subjects, the passing of technical examinations and of understanding the impact of her works on the rest of society.

Unfortunately, although it is in many ways a challenging technology, electronics, communications and software, has been an engineering field in which it was/is relatively inexpensive to learn design by practical construction. Compare building a ham transmitter to building a bridge. To a great extent the fields of engineering associated with ham radio: electronics, software, are accessible to "weaker" cousins more so than those of other more venerable and demanding Engineering disciplines. This is evidenced by the practical and commercial success in our hobby and industry of shoddy, individuals, companies and so called designs which just would never pass muster in truly demanding Engineering fields. And so... even partially rounded, persons can "claim" to be engineers in most fields of interest to hams. The field of software "engineering", one of the newest disciplines, is especially rife with charlatans and rip offs....

How many would feel comfortable flying in a 767, staring at a screen in the cockpit presenting a blinking message "If you don't want to see this message again, then next time shut down the plane properly"... now checking for errors... or while crossing the Golden Gate, being asked if you want to "abort, retry, or... whatever" before continuing your trip, or riding an elevator to the top of the Sears tower staring at a button that says "reset" and wondering why the hell did they put that button there?

Engineering indeed!

Let's first try to get the definition of Engineer understood, and then try to decide whether being a ham before, during ,or after the intiation into that sacred sisterhood is aided or abetted by the "ham experience".

Thoughts, comments?

Source record: 149676

Tom,
Your '746's manual means that you shouldn't try to use
balanced feed line, just a 50 ohm, unbalanced feedline. It
doesn't mean you can't use a G5RV antenna. Your internal
tuner may not be able to handle the impedance differences that
a G5RV presents on bands other than 20 meters, though.

sure, I'll make the test plan available for all for comment once
we gather sufficient informations about what we have and how much
time we can spend for testing.

> As for the full size Standard Antenna, or a much smaller one, there

Stefano told me (and others) several times that the EH is 2 to 3 dB
better than a full size dipole. Now a full size dipole, as far as I know,
is an half wave radiator fed in the middle. Using an end fed half wave
vertical just allow us to handle better the reference antenna, i.e.
there's no need to rotate it as we change receiveir position, there's no need
to put it up an height at least equal to half a wavelenght and also I believe
that EH radiates vertically polarized.

> larger one (the poor, known, antenna already establishes that fact).

that again is why we'll try to compare it to a small antenna. Though, as
you suggested, there might be differences in tuner's wasted powers.

> Myself, I am not terribly concerned about induced or conducted

I tend to agree with you, but blocking and measuring currents on the
coax braid will be easy enough I think. We'll try to avoid the use of
metallic supports for any transmitting antenna also.

It would work. Keep the ATU box small, mount it on 3 tall porcelain legs and wear a thick, high-voltage, electricians' rubber glove when adjusting it.

Or instead of 3 porcelain legs suspend the ATU on a dry string from the ceiling.

Such arrangements always impress visiting novices.

Putting a choke balun in the transmitter 60Hz power lead is not recommended.

Well, that was another question. Since the shield and the center wire
are attached to the coil only 3 turns apart, isn't it shorted there?

Patrick

Yes, DC-wise. No AC-wise.
You'll have to disconnect the center wire at the
coil b4 checking with an ohm- meter.

As it turns out, commercial tower companies, cell phone companies,
power companies, etc, have been using galvanized steel for several
years now. Copper may be better to start, but after several years the
galvanized holds up better.

Thanks Mark,
that's the first time I've seen any reference to it - knowing it to be true.
The Ferrite rod receiver is quieter on interference even when you nul out
(or nearly) the station. It is a seriously different order of magnitude of
interference.

Another question. What about hanging a ferrite aerial on the back of a
receiver that was not designed to take one. Or put up a multi-turn loop
between the aerial and earth sockets with some kind of impedance matching
transformer?

thanks again

Spencer

My sentiments exactly. Having worked in excavation in the past, plenty of tamping would be prudent, and also including extra dirt on the surface to fill in around the pole as it will still "settle" a bit. One thing he may consider is setting the thing up with concrete at the base.
It may be worthwile to do this if the cost permits. 8 feet deep by however wide may help assure that this pole would stay put. Just some thoughts........

The average T-net antenna tuner can be tuned worst case for a match. There
are multiple settings. If the setting is made using maximum inductance,
the losses will be greater than if made using minimum inductance. Just
a thought. Are you using minimum inductance?

That would be a DC short but not an RF short. What I am asking is: have
you checked your coax for shorts with the coil disconnected? Is the coil
performing an autotransforming function at the antenna?

These are flip sides of the same coin. I used the word "correlate" in
a statistical sense. Yes, there will be good test takers who are also
very pragmatic, practical people. There will be test takers who are
completely clueless. There will be practical people who can't pass a
test if their lives depended on it...

What I'm saying is that performance in formal educational studies has
very little relation with performance in a practical setting. Yes,
you see people who can do both very well, yes, some are only good at
one thing or the other, and some will never do well with either.

>How many kids use the stupid excuse: 'But Einstein was a poor student' and

>academies and European gymnasiums because he, in fact, was a good student.
>We seem to want to believe poor grades, bad academic performance, and lack
>of theoretical knowledge is a good thing. I suspect that this is an american
>concept; we don't want anyone to 'feel' bad for not making the grade.

I think you read more in to this situation than I do. I see a
contrived situation in a classroom and people feeling stupid because
they can't relate their own experiences to a severely limited
scenario. It is then that we need to be reminded that school
performance doesn't correlate well with performance in other similar
endeavors.

>I think of tests as goals because I know that while I reach for a goal I'm
>also learning the important stuff along the way.

Learning stuff is good. Applying what one learns is why most people
learn in the first place.

I look at most tests as a means to an end. It's a preliminary and
limited "proof of performance" to show that someone is at least aware
of the fundamentals. The key is whether that person can translate the
fundamentals to real world applications. Seeking a good score on a
test for the sake of scoring well on a test is to have missed the
point.

Mother nature doesn't care what you scored in the classroom. I don't look for good pilots by seeing who did best on the written exam. In fact, that score is completely irrelevant. I look for people with experience and mature judgment.

Do you still include the GPA you received in college on your Resume? I didn't think so...

"As it turns out, commercial tower companies, cell phone companies, power companies, etc. have been using galvanized steel for several years now. Copper may be better to start, but after several years the galvanized holds up better.'

There is more to the story or the companies named are all wrong.

Galvanized coating is zinc. Its virtue is that it is at the opposite end of the electromotive series from steel, which it protects by eroding instead of the steel rusting away.

The electromotive series lists metals in "decreasing order of their tendencies to pass into ionic form by losing electrons" (CRC Handbook).

The sacrificial anode protecting ship hulls and other metals around the woprld is called a "zinc". The zinc is eaten away instead of the steel.

Two common metals are more active in eroding in an electrolyte. They are aluminum and magnesium. But, zinc is the metal of choice for most protective anodes.

A pretty good primary cell can be made by copper and zinc in a saline solution. When current flows, the zinc erodes, not the copper.

Best regards, Richard Harrison, KB5WZI

Yes, it worked reasonably well...

Then as an experiment, I hooked another 5 metres of wire onto each end bent round
the outside of the attic, hooked about 9 metres of 300 ohm twin between the feed
point and the coax, keeping as much of it vertical as possible (high ridge to the roof!) and
ended up with a full size G5RV bent round to look like an old VHF "squalo" - it tunes
up on all bands from 80 up though the radiation pattern is a bit weird!

"It is then, we need to be reminded that school performance doesn`t correlate well with other similar endeavors."

Any statistics to support that assertion?

Learning is remembering what you`ve been exposed to. Tests are given to discover if you`ve learned.

A "similar endeavor" requires remembering what you`ve been exposed to for some other purpose than a test. The same ability is required.

Training may require physical abilities in addition to mental ability. Animals, musicians, athletes, etc. are trained.

>

Hi Francesco,

This kind of specification
>Stefano told me (and others) several times that the EH is 2 to 3 dB
>better than a full size dipole.
is exactly what I was speaking about. This has all the hallmarks of
an escape clause that allows the poor debater to argue the merits of
ANOTHER antenna rather than his own.

A full size dipole? I won't descend to ask them just what size that
is. No, if they cannot beat an antenna the same height/elevation,
there is no other appeal to confusion.

As for
>also I believe
>that EH radiates vertically polarized.
That too suggests some confusion as to what is being measured,
especially when the debate is couched in terms of full size dipoles.
The common experience of these is horizontal operation. We here on
this board could cynically agree that yes, the EH's vertical
polarization is as poor as a Standard Halfwave Horizontal Dipole and
walk away from the debate satisfied. However, I wouldn't want to hear
from Stefano about how no one understands that the special
electromagnetics of this invention allow it to be a horizontally
optimized radiator that was never properly tested (as such).

In short, there is no reason to proceed before you get the sign-off
from the proponents that your test grid will cover all characteristics

that are important and meaningful. You might be surprised how difficult this last requirement may be.

You can protect against direct strikes even while operating, but it's
not exactly cheap, and it's not simple.
One single mistake and you will have problems.

That's what "lightning arrestors" are
> for. Read the ARRL handbook on the subject of grounding. Basically it
> tells you to use a lightning arrestor on each line coming into your house,
> to ground them *outside* the house at the entrance and to bind that ground
> to the electrical service ground. They also suggest using some sort of
> interruptor *outside* the house to disconnect everything when the radios
> are not in use.

A good idea. Even if the cheap arrestor doesn't protect the radio, it
should keep the bulk of the energy outside as long as the connection to
ground is good. In his case, the single most important thing he can do
is have a VERY GOOD ground connection from the roof mast to ground. You
really want to have the ground rod/rods/radials near and below the mast
, and have no sharp turns. I would want to use copper flashing that is
intended for this job to have a good path to ground from the mast.
Polyphaser has that for lightning rod systems. You could use thick gauge
wire, but I think the wide flashing is better. If you can direct the
strike to ground efficiently, you have 85% of it licked. I'd use the
arrestors as a way to protect the house, and I'd have a way near the
window or whatever to be able to unhook and ground out in bad storms.
Even a grounded antenna switch near the window with a ground position
would be better than nothing. I unhook mine and ground out outside to
so-239's. I've taken two direct strikes on my mast in about the last 3-4
years, but had zero damage. My mast efficiently directed the strike to
ground, and the rest on the coax just went to ground at my window
"bulkhead". There was not enough energy on the coax's to cause any
damage. The mast did 95% of the work I think. But I use a metal mast on
the side of the house, not on top. It's a lightning rod. What he wants
to do is turn his roof mast into an efficient lightning rod also. Thats
what it's going to think it is, if it gets struck. If no good ground
connection, it will find one, and I bet you won't like the path it
chooses. :(And high resistance means high likelyhood of firework type
emulation. It could easisly start a house fire. With a good ground

connection he should be fairly safe. MK

Hi all,
Tamping is great if you are going to put something onto the tamped down surface and don't want it to move, like a wall foundation or a concrete slab. As far as keeping the pole from moving, I would suggest it would only be marginal at best. Once the earth is disturbed the best way to get it to settle back into a condition anything like it was pre excavation is to backfill and water it down as you go. Then just to be sure use a pipe on the hose to insert into the disturbed sections and see how much more it settles. The best method is to have a hole drilled and set the pole into the hole, then backfill with dirt or concrete. Safety first. BTW does anyone out here know of a company (construction) looking for a Safety specialist, OSHA Outreach Trainer, preferably in WI or North/South Carolina? I know, It's of topic, but a guy has to get money for radio and fishing stuff somehow!!!

No. How does one evaluate a person's ability to translate learning in to real world applications, anyway? I wrote that I used the word in a statistical sense, not that I had any statistics to back it up.

>Learning is remembering what you`ve been exposed to. Tests are given to
>discover if you`ve learned.

That's what I'd like to believe, but my experience is different. Most tests are given to see if you *remember* what you've learned in the context in which the test is given. Classrooms are contexts in their own right.

>A "similar endeavor" requires remembering what you`ve been exposed to
>for some other purpose than a test. The same ability is required.

How I wish that were true.

The memory systems of Homo Sapiens tends to be associative. In other words, things are remembered in the context they are most commonly used. It's not surprising that so many learn things in the classroom that they can't relate to the real world.

Thus I posit that most tests only demonstrate knowledge in the context of a classroom. Whether that classroom context can be applied to the real world is a different story. That's why I think a ham radio background can be relevant to an EE student. It can provide them another context to remember the concepts they learn in class. And in doing so, it can help associate many ideas learned in the classroom in to the real world.

Another area where the ham radio license used to be pretty cool: When morse code was commonly used, it was a wonderful performance test to use on hams to use their radios and experience to improve their morse receiving speed. As a performance test, it had a definite practical hands-on aspect. Unfortunately, Morse code is about as relevant to radio as horses are relevant to transportation. Yes, both are still used here and there, but for the most part, they've been superseded by better technologies. I wish we had a better performance test to

replace morse code.

>Training may require physical abilities in addition to mental ability.

If it's bigger, then it may help you hear further, thereby increasing range of your radio in a 'technical' kinda way.
What I find interesting is the 'stinger' matching piece on top. I'd bet money that even at 1Kw, it'd become a bright orange piece of flaming metal. 15kw?.. I suppose that's a safe bet, since who's going to try it at that power??...

The big exception being home (and perhaps other) water heaters. The protective anode in home water heaters is usually magnesium or aluminum (10 years ago aluminum was almost unheard of, but it is very common now).

2124. Re: EH / Crossfield Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-30 22:45:05 UTC
From: "J. Harvey" <JM001.Harvey@sympatico.ca>
Message-ID: <FH_58.14233$DE3.2361995@news20.bellglobal.com>
Source record: 149711

I've been asked (off-line) how one might approach the problem of obtaining (complete) elevation pattern data for such an antenna. The purpose being to enable the complete picture to be gathered and sanity-checked against 0 dBi (100%).

Ah, step 1: Why not follow the industry standard and make the first model scaled to a frequency such that it would fit through the door of your local anechoic chamber. Making the 'first' prototype (if that can be said of an EH antena...) suitable for operation in the HF frequency range is just silliness.

As far as the dual E+H feed and/or matching network is concerned - eliminate that part of the equation. Beg, borrow, rent two individual signal generators that can be phase locked. This way you could vary the amplitudes and relative phases till the cows come home. Assuming that you account for the double input (ah... x2), it should eliminate that unknown part of the system.

Jake, AB3A wrote:
(Animals, musicians, athletes, etc. are trained.) "And so is
thought.--Your point?"

Memorizing a list of facts is education. It may also be a work requirement. A test proving you are able to remember a list of facts may augur well for work performance.

Jumping through hoops or some other physical act is proved by physical performance. Stuffing parts in a board, then soldering them in place requires physical performance in addition to mental performance. The physical is training or making conform to a particular discipline. It is a little different from recalling miscellanea.

I think I mostly agree with your posting.

I insist that memory content testing is indicative of likely mental performance on the job and in school. Notice, I said indicative, not predictive. In other words, it is not 100%, but the odds are with the testing, that is why it is used.

Best regards, Richard Harrison, KB5WZI

Seems to be an attractive price for most CB related gear.

Sure I am a fan of a wide bandwidth antenna, but I consider looks as well.
You should have seen the looks I got with the BB3 screwdriver mounted on the
back of my Intrepid! Least I had the sense to paint it to match the car!

Sylvan Butler wrote:
"The protective anode in home water heaters is usually magnesium or aluminum (10 years ago aluminum was almost unheard of, but it is very common now)."

I am not a cathodic protection engineer. I don`t even play one on TV. My education is a half-century old. "In my day", zinc was almost universal. In WW-2, I changed out exhausted zincs in heat exchangers and other protected structures aboard my ship.

Zinc probably produces enough current in most instances for protection, and doesn`t erode as fast as the more active aluminum and magnesium. So, it wouldn`t have to be replaced as often. The current price of metals (pun) may have something to do with their choice.

A steel-zinc battery doesn`t have to be made to protect the steel by mking the zinc migrate toward the steel instead of the steel eroding and migrating away. A current can be impressed on the steel and an inert carbon anode by using a "rectifier" or other d-c supply of the correct polarity. This ensures current is always flowing toward the steel instead of away from the steel. This has the advantage of not eating zincs.

Best regards, Richard Harrison, KB5WZI

2132. Re: interference

Newsgroup: rec.radio.amateur.antenna

Source record: 149718

I have seen large loop antennas advertised on the web used for augmenting AM
reception. Look for it. It does not need to be connected to the receiver
but simply couples into it. Any loop is good, it does not need to be
ferrite loaded.

Mark

MSC wrote in message ...
+AD4-Thanks Mark,
+AD4-that's the first time I've seen any reference to it - knowing it to be
true.
+AD4-The Ferrite rod receiver is quieter on interference even when you nul out
+AD4-(or nearly) the station. It is a seriously different order of magnitude of
+AD4-interference.
+AD4-
+AD4-Another question. What about hanging a ferrite aerial on the back of a
+AD4-receiver that was not designed to take one. Or put up a multi-turn loop
+AD4-between the aerial and earth sockets with some kind of impedance matching
+AD4-transformer?
+AD4-
+AD4-thanks again

Netiquette Guidelines

3.1 User Guidelines

3.1.1 General Guidelines for mailing lists and NetNews

If you are sending a reply to a message or a posting be sure
you summarize the *original at the top of the message*, or
include just enough text of the original to give a context.
This will make sure readers understand when they start to
read your response.

Since NetNews, especially, is proliferated by distributing
the postings from one host to another, it is possible to see
a response to a message before seeing the original. Giving
context helps everyone. But do not include the entire
original!

One problem is that many of the upside-down posters don't bother
to trim attributions; they stick their comment at the top and
leave everything trailing below so that one is never sure what
point in a multiple attribution repost they're actually responding
to.

The considerate poster, and there are many on these newsgroups,
will show a trimmed attribution and his or her comment below
after a white line separator.

You've no idea of the havoc that upside-down postings causes with text-
reading programs for the blind such as JAWS.

Visit one of the more academic newsgroups in which posts are
frequently responded to point by point, and you will see just
how important chronological posting is.

Does not look like it...
I saw one of these amps last year...
Although very illegal, I found it very interesting that someone
would go through so much expense to run this kind of power on 11 meters.

The one I saw took the whole rear of an enclosed pickup truck.
Out of curiosity, this guy proudly showed it off, and showed me
his output on a Bird Meter. He was running a Amateur rig on 11 meters
to drive it.

There are people that run that kind of power, although generally not on
a day to day basis.

A standard whip handles 1 KW without getting hot. No idea what would
happen if you fed it with 15 KW.

What is an autotransforming function? The purpose of the coil is to
inductively shorten the dipole.

I just got back from the antenna and found that the center conductor
had snapped off. After soldering everything back together and making
sure there were no shorts, I checked the receiver again, and I only
get a signal if I attach the center conductor. If I attach the shield
to ground, I get no signal.

I've seen a setup to get full hemispherical radiation patterns. It was at the Naval Research and Development Center (NRaD, formerly Naval Ocean Systems Center NOSC) in San Diego. They had a rotating platform about 50-100' in diameter covered with hardware cloth. There was an arch overhead that the detector could move along. The model was put at the center of the platform, and the feed cable went through a hole and back under the platform to the test building. Between rotating the platform and moving the detector along the arch, they could get a full pattern. They had wonderful hand-built brass covered scale wood models of every class of ship in the U.S. Navy, which they would put their model antennas onto for testing. Quite a setup. Incidentally, they also extensively used NEC for modeling the same antennas, and compared results, I believe with generally good agreement.

I don't think it's possible to get a decent 3D pattern like this with much less of a setup. In an anechoic chamber, you'd have to use a physically small detector with a fiber optic link (such things do exist) to avoid interconnecting cables interfering with the pattern. And you'd have to devise some way of positioning the detector without introducing any conductive materials in the field. It would be possible but pretty tricky. Anyone attempting to do something like this would have to first carefully measure one or more reference antennas with known patterns (and would likely be disappointed by the first results). Outside, you'd just about have to use a helicopter. But it wouldn't be easy to keep the helicopter itself from modifying the pattern.

> system.

I think the difficulty here is in, as you say, accounting for the double input. With the very highly reactive loads, it won't be easy to make a good determination of just how much power you're feeding into the thing.

The claims for the EH antenna's performance presumably include "phasing" network losses. So I suggest letting the EH promoters provide the network along with the antenna, and test the whole thing as a system. If the EH antenna can't provide good performance using a network that can actually be constructed, it's of no real use regardless of any possible theoretical capabilities. After all, the only reason a teeny tiny short dipole or monopole isn't just as good as a full sized one is because of the losses in the wire and the matching network you need in order to get power to it.

I won't comment on the antenna, but a balun is very important for this application. It prevents the feedline from picking up some of the signal and feeding it to your receiver. For direction finding, you want to be using the antenna, not the feedline, to figure out where the signal's coming from.

I wonder what the chrome does for RF skin losses? I also remember someone (W8JI ?) doing an analysis of what is wrong with using a large center mounted
coil.

Pete,
The 'problem' with using a center mounted loading coil are
the resistive losses of the coil (common to any loaded antenna),
and the mechanical problem of mounting the coil. Depending on
the frequency used, you end up 'eating' the resistive losses,
that will happen with ~any~ loaded antenna no matter if it's
base/center/top loaded.
The 'chrome' shouldn't make any appreciable difference to
'skin affect', unless the metal is heated to the point of the
chrome loosing it's contact with the steel core. Of course,
the corona discharge will probably 'chew' the antenna down to
the coil before that happens.
The 15 KW claim is pure 'horse-hocky' (to put it politely),
but there are people stupid enough to do what's necessary to
run that much power mobile. You can tell who they are on the
highway, they're the ones who drive the 20 ton alternator with
wheels on it...

I had a friend who was working at a trucker/bd stop in Arizona. He
was putting amps together, mobile and SB200's, and altering the meter
shunts to reflect high power (KW or so). He would set them to run no
more than 30-40 watts. Made a bundle! Selling them for $1000 plus!!

He also made mirror antennas (phased and high gain ...[20dB???]). He
was getting 300+ for those and paying less than 40!

> formerly Naval Ocean Systems Center NOSC) in San Diego.
> <snipped only for brevity>

Yes, I have seen some of that very setup along side of the road heading out to Cabrillo National Monument. I knew exactly what they were up to since they had some of those brass models of ships that you mentioned stacked up outside next to the fence. [Coincidently, I'll be back in San Diego next week... ...the temperature was about 42F (=9C) there today. :-(
!]

> I don't think it's possible to get a decent 3D pattern like this
> with much less of a setup.

Perhaps not always true if you think about it. The size of a ship as compared to the wavelengths (both scaled) under investigation mean that it could produce a fairly complicated pattern. The pattern in such a situation could be, in the worst case, as complicated as a porcupine (hedgehog for our UK listeners).

When you're talking about an antenna that is only a small fraction of a wavelength in its maximum dimension, you can only achieve a certain separation of the contributors to the overall field. Therefore, the gain pattern in the case of the EH antenna should be fairly smooth and changing fairly slowly in both azimuth and elevation (perhaps with several nulls to not overlook !). In other words, you don't need to use a complicated arrangement with stepping motors and so forth to test such an antenna (that is DESIGNED to be "small"). One can assume that the rules of basic mathematics still apply.

You should be able to poke and prod to get perhaps 50 to 100 data points, as well as a general check for the overall shape, and then you could simply connect the dots using the appropriate curve (sin^2 ?). Once these data points were in MS-Excel, one could proclaim that the average gain was about -0.33 dBi (or whatever the feed network losses are), and that the forward peak gain was +1.3 dBi (or whatever).

> In an anechoic chamber, you'd have to use a physically small detector
> with a fiber optic link (such things do exist) to avoid interconnecting
> cables interfering with the pattern. <snip>

Such chambers and skills exist in numerous locations around the world. The standard practice is to scale the Unit Under Test to a sensible frequency (~2 GHz) where the RAM (radar absorbent material) is effective. The sensor

and support arm are covered with RAM. It is standard practice.

> Outside, you'd just about have to use a helicopter. But it wouldn't be
> easy to keep the helicopter itself from modifying the pattern.

No, scale the darn thing to (say) 2 GHz and (if they insist) use a remoted controlled model helicopter in the chamber. :-)

> I think the difficulty here is in, as you say, accounting for the double
> input. With the very highly reactive loads, it won't be easy to make a
> good determination of just how much power you're feeding into the thing.

Couldn't one feed such a 'highly reactive' animal through a pair of 20 dB inline attenuators (one for each feed as I mentioned in a previous posting). Obviously, one would have to remember to account for the attenuators, but they would certainly isolate the reactive "chaos" from the generator. Worst case, add a directional coupler and measure the reflected power separately.

Obviously, the selected scale frequency shouldn't be too high such that we humans (in the year 2002) can't measure the actual power in the face of a reactive load.

Darn good point. One thing to allow "Them" is that room temperature superconductors may arrive on the scene anytime. There are apparently (new thread ?) actual antenna products on the market now that makes use of superconducting technology to achieve the otherwise impossible.

I don't believe that it is worth the effort to "test" antennas at HF until you have already proven (!) all the theories at a more convenient and trustworthy frequency (like 2 GHz).

Patrick,
In effect, the coil from the connection of the center
conductor
of the coax to the begining of the antenna is to inductively
lengthen
the antenna. From the center conductor connection to ground is
the
part of the coil that 'matches' impedances. Which is all beside
the
point since you found your problem...

>

Why don't you like the ATAS100? It's not my favorite choice and indeed is very limited, but what do you want to do? Do you want the best all around setup, an unobtrusive setup, one that mounts easily, or just the best bang for your RF output?

For a single band like 75 meters or 40 meters, your best choice option would be a large center loaded whip like a BugCatcher. If you want to be able to move around on HF from band to band without getting out, one of the screwdriver antennas would be a good bet, (this incidentally is also a center loaded whip) assuming you can mount it properly. Unobtrusive is more difficult, it becomes a question of deciding what you want. You can get a lot of HF contacts with 5 watts, but the less your antenna, the less likely you are to be happy, and unobtrusive can be taken as a synonym for doesn't radiate well sadly.

Okay.

$139 each ? Ouch. Forget the balun - it should have a nice, tuneable
preamp with a balanced input.

Engineering is continuous learning plus a mix of theory and practice.
Sometimes the ham radio experience helps, sometimes it hinders.
The theory helps design things, the practice helps debug them.
Good use of theory makes designs repeatable...

The chrome IS nice. Nice looking. I think that heavy chrome plating resonates in the American psyche with the strength and purity of the 1950's when chrome was thick and cars were heavy and power was POWER. It looks like it could handle 15,000W with chrome to spare. I can just see that baby on a dark night glowing orange and blue blowing out neon lights as it cruises down Main. WOOWEE! HOT DAMN! We're smokin' now!

I think it's worth $150 just for decoration. I'll take two. One for each mirror. That means 30,000 Flaming Watts of ....GREAT BALLS OF FIRE!

Doc, if you supply the alternator, I'll supply the pickup and together we'll make internet history. You drive and I'll take the video.

2169. Re: Ladderline matching/SWR when wet?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-01-31 06:51:51 UTC
From: googlyelmo@earthlink.net
Message-ID: <3C58E97B.253A5A04@earthlink.net>
Source record: 149655

When I posted the query that started this thread, I had just installed my antenna system here, and enjoyed an unusual string of half a dozen days of real live sunshine (not the norm in late december in Seattle. . .). Since then, it has rained, and snowed, and rained, quite a bit, maybe 6-7 inches total. What I am finding is that the moisture doesn't seem to have much of an effect on matching, or on received signal strength. This antenna, almost identical to one I had when I lived in Arizona, but for the climate (and *slight* difference in ground conductivity, hi!), and it is performing better, in spite of the rain. I can only guess that while it rains often and for extended periods here, it doesn't usually rain very hard. Commonly our precipitation at this time of year resembles an extremely heavy mist more than anything else. Perhaps the caveat about wet ladderline applies more typically to summer storms in the Midwest and Northeast? So I am keeping my fingers crossed. So far so good. Thanks to all who replied, I learned something, as usually I do amid this group.

"Contribute" What? To whom? By whose mandate?
If I laid out a five page list of what I've done
since passing the Extra class exam 32 years ago, you'd just troll
right past it and declare if to be of no "value". If you think I laid
down and expired after passing the Extra class license test you're
even more obtse than you're shown yourself to be in the past.

Seems you haven't exactly loaded up ham radio with contributions
yourself, despite claiming all sorts of expertise in "new mode"
development. I guess you don't deserve any respect.

And of course, to you that means dreaming up some new digital
mode etc. ad nausum. You're a clone of Karl Stevenson, as though
we needed another one.

If I had never done anything else, when the VE testing system
started I started and ran a VE team for eight years, and there are
hundreds of hams who would have not had the opportunity for
licensing if not for that team. We licensed so many new hams
during that time we put ourselves out of business since several other teams in
adjoining areas started from those hams. Meanwhile you had so mild an interest in
ham radio you didn't bother with an Extra ticket at all util it became a freebee.
When you can top that for "contributing to the ARS" get back to us.

OK maybe the ATAs 100 is a good antenna as long as its RF capabilities
are concerned - but mechanically ? I worked with one - after 6 weeks
the auto adjusting gear broke - got a replacement antenna, 8 weeks
later the same thing happened. So I decided to give it back. What I
would like to know if there is something similar but not ATAS 100....
at the moment I am working with a G5RV but this does only make sense
when staying at a place for a longer time.
I am thinking of a XR-100 mini portable dipole - any comments to that
one ?

Regards, Joe

It's not the whip - the mechanical parts did not convince me working
with it - auto adjust gear broke twice.

Regards, Joe

Lets see ... on a 13.6 volt system that would be approx 2205.88 amps using a 50% efficiency for the final class C power amp. Anyone have a trailer mounted gen set to load up this antenna?

heh heh!!

No he has not found the problem AFAI understand.

Quote:
"If I attach the shield to ground, I get no signal."

He must again remove the centre conductor at the
antenna end. And than, by using an ohm-meter check
the resistance between the centre conductor and the
shield of the coax.

Then, there is this messing around with autotransformer:

Antenna -------X
X
X---------- Shield
X---------- Centre conductor
Antenna -------X

Note that the coax SHIELD is supposed be connected to the tap
in the CENTRE of the coil, otherwise this device will NOT work
correct! The drawing at
http://www.flashwebhost.com/circuit/shortant.php
is WRONG!
However, You should detect a signal, also if the antenna
is made according to the link. And You should be able to
transmit power, but Your coax will radiate, too (which is
not the purpouse of a koax), and this might produce TVI
and other unwanted phenomenons (RF ewerywhere in the
shack...)

The autotransformer thingamajig in the middle of Your antenna
has TWO purpouses (correctly connected) it this particular
case:

1) Shortening the dipole inductively
2) Act as a BALUN- transformer

Well, maybe I'm totally wrong here, but simply I think that comparing
this EH to a half wave vertical and to a short vertical having the same
height of the EH, in the same position would suffice. If the results
are as many of us think they should be, and the test is perfectly repetable,
what else they could argue?

> silliness.

Ask the "inventors". As far as I remember they say there're "lossess" in
the matching network. Recently an italian HAM said he successfully made
a 50 MHz EH prototipe, which could be tested in a local military anechoic
chamber which is surely big enough (they make EM tests on elicopters there...);
I suggested this approach but I haven't seen any reply so far...

> As far as the dual E+H feed and/or matching network is concerned - eliminate

As far as I know, the inventors say they have put current and voltage
in phase on a capacitor. I don't know how could I obtain this with any
number of signal generators. But maybe it's just me, and all those professors
I had at university....

139 dollars. Not cheap.... You can make a nice one Yourself
for about 1/10 of that price.

And, for HEAVENS SAKE use a BALUN (if used for ADF).
Well, it's nice if you get max. signal strength when You
aim at the target. Without a balun You'll get a declination
-as with a magnetic compass, at least here in Scandinavia
NOT pointing straight North

(If You succeed in obtaining a balanced input preamp or a
RX with balanced input front-end, You do not need a balun)

I agree with Francesco; let's keep things simple in the first place. Tests in an anechoic chamber can be done when the high-frequency prototype will be available; but please keep in mind that losses due to conductors DO NOT scale properly with size, unless you "scale" also the conductivity of the material. I mean, if you measure an efficiency of, say, 70% at 144 MHz, you won't find the same efficiency if you work at 7 MHz with an antenna properly scaled in size.

Anyway, I shall be happy for now with a test like the one that Francesco is proposing. In fact, being almost a point source, I don't expect a high directivity from the EH antenna - the directivity function shall be pretty much like that of a dipole; but we must be most sure that the feedline is not radiating, and this can be achived quite easily by using ferrites.

If the antenna works like a dipole, that's fine for me ! It is very compact... I just regret that I am too stupid to understand the theory behind it.

Sure.

It is a compact 40 meter dipole for limited space application by Jact Sobel W5VM. It is a center loaded antenna with a loading coil at the center. The two arms are 18 feet 6 inches long connected to the two ends of an inductor at the middle. The inductor consists of 30 turns of 12 SWG enamelled copper wire wound on 2.5 inch diameter PVC tube 5 inches long at six turns per inch.

The shield of 50 ohms coaxial cable is connected to the center of the coil. The center conductor is connected to 2 or 3 turns away from the center, to a point which gives the lowest SWR. (right now at 2 turns)

So:
<- 18'6" -> <- 18'6" ->
------------\\\\\\\\\--------------
| |
^ |
shield |
^ center conductor

On the receiver side (MRX-40), the center conductor is connected to the antenna input to the receiver. The shield is connected to the ground of the receiver which is connected to the negative terminal of the battery (9 volt).

I used to work for a major Cell Phone company, as an RF engineer. I
don't ever recall seeing a copper ground system. They were all
galvanized, and what I read was that they last longer.

I don't know what the reason is (if its longevity or cost), but that
is what is being used nowdays for commercial installations.

This brings back some found memories. In addition to the San Diego setup (I think its now called Space and Naval Warfare Systems Center San Diego SSC SD), the Navy also had one on the east coast (NRL) that closed sometime during the early 80s. Several commercial companies also had similar setups, built scale brass models at 1/48th or 1/50th (convenient for metric) scale and performed full hemispheric pattern measurements. The rotating turntable was approximately 22+ feet in diameter to accommodate the aircraft carrier models. At the early San Diego setup (NEL at the time), conductivity between the turntable and the rest of the ground plane was maintained by filling a circular trough with mercury (no MSDS sheets back then).

Wood was only used in the model to construct the basic hull frame for the ship. Everything beyond the hull structure and above deck level was all brass with no wood support. These highly detailed models would take some 8 - 12+ weeks to build by hand. This was really an art.

Enough digression ...

I'm afraid that this aproach misses one important point.- ANY departure
from the set-up and configuration the proponents have made is grounds
for them to say that the tests were not of the system they are pushing.
This has been true of the CFA, and of most of the other systems that
claim new physics.
It does not matter that your approach is tried and proven, and nearly a
standard. If such a test proves them right- they will grab at it, but if
it proves them wrong- it'all your fault, not the fault of their antenna.
I suspect that even the use of a common-mode current block will be
claimed to be a violation.

If you rested on your laurels after passing the Extra exam, your list
will be empty. If your list is not empty, you didn't rest on your laurels.

My thing is antennas, not new modes. For years I have maintained
antenna web pages and written magazine articles on antennas. As
far as I know, my binary ladder-line length selector is an original
contribution.

Jason Hsu wrote:
I would expect to see that EE hams, as a group, earn better GPAs---."

Later someone asked:"Were there any EEs in 1920?"

There were hams then. The ARRL was formed in 1914.

There were alse EEs, long before 1914.

Nikola Tesla may have been the most important EE who ever lived. He invented the a-c power system.

Tesla graduated from the Higher Real Schule in Carstatt, Croatia in 1873, then weent on to the Polytechnic School in Gratz with the intention of becoming a professor of mathematics and physics. But, Tesla switched majors after tinkering with a Gramme dynamo in the physics lab. Inspiration for the a-c power system had already struck him. Tesla switched to the engineering curriculm.

On graduation, Tesla continued his education in Prague and Buda-Pesth to learn languages so he could read widely and work almost anywhere.

Tesla got a job in Paris as an EE with a electric lighting company.

In 1888, Tesla began serious experiments with his rotating field (polyphase) a-c machines.

Tesla decided the US would offer him the best opportunity to exploit new ideas.Tesla had an introduction and letter of recommendation to Edison. When Tesla arrived, Edison said there was one of his machines broken on a boat and if Tesla could fix it, Tesla had a job.Tesla made short work of the repairs.

Tesla and Edison soon parted company. Edison hated Tesla`s a-c power ideas. Edison`s investment was completely in d-c machinery and he wanted to keep it that way.Tesla eventually found a backer in George Westinghouse.

Tesla`s first publication beyond his patents was a paper presented to the AIEE in New York in May 1888, in which Tesla showed how to throw away the commutator in electrical machines. He wowed them.

So, there were certainly EEs in 1920.

OK, Y'all gurus fire off them infernal Babbidge Engines! Dunno about Joe's but my motorhome is made of a nonmetalic "sandwich" and is big enough that I could run a 20m dipole horizontally across the roof. As an alternative to "car" solutions, how about a random wire (for lack of a better description) on standoffs in a loop around the roof?? Ground side would be the metal frame under the vehicle? Predictions??? Advice???

Dick, if you really did that, then you did NOT rest on your laurels
after obtaining your Extra license. A few of us are ragging on hams
who contribute nothing after obtaining a license. Why do you think
you are in that catagory and have to defend yourself? Is your
conscience bothering you?

FYI, Patrick, that's an autotransformer in the center. See Val's posting drawn a little differently. Disconnect the center conductor and check for a short between the center conductor and the shield. Also check for continuity between the two ends of the antenna. Check for shorted turns on the coil.

[snip]

It has been my experience that your comment is very often true. Don't know for sure that you can really blame the students though...

Unfortunately for the students, since it is not always in their best interest, the academics who teach them at engineering schools do not often abuse the students of that idea.

The four year academic program in engineering is nothing more than preparation in the analysis of engineering problems. Certainly that is *one* of the skills required of a design Engineer, but only *one*! The graduates of such programs are only so much "putty" ready to be moulded into an Engineer in the fire of the workplace, and as some on this thread have noted, a large percentage of them never make it. Much more training, learning, and a long practical apprenticeship is needed to complete the process of creating a great Engineer.

Academics need students to stay in business, "headcount" is king in US Universities at least. "Headcount" is what drives budgets, etc...And telling beginning students *explicitly* that the academic four year program they are taking does *NOT* qualify them to be an engineer is not encouraged. Hence some/many will graduate thinking that they are Engineers, when they are only wannabe engineers, and still have a long path to become a real Engineer.

Some/many, I might add, never do!

Think what you want. I quickly realized it was more interesting to design, build, and troubleshoot equipment than to sit there playing with it. My interests were elsewhere. Over the last 35 years I've helped a number of hams either get on the air, or stay on the air. I've done the same for three TV stations and about a dozen AM radio stations. Right now i am looking into the chief engineer's job at another TV station.

If you enjoy using the equipment that's great, but I would rather spend the time studying a new computer language, or work on a new receiver design. I was part of the team that built a custom telemetry receiver based KU band uplink system used for video and data transmission that is on the space station. I worked with the embedded controller, power and data distribution system, and the video system that allowed recovery of signals from 10 KHz to 20 Mhz. Not everyone has the same interests or hobbies.

Find an area you enjoy, and have some fun.

Take care, and God bless.

Or that the first English colony (Roanoke Island) disappeared entirely,
every man woman and child lost, or that 4 in 5 died in the next
(Jamestown), or that there were more slaves in N.Y.C. than in Richmond
circa 1800 or that ... etc.

That's not PC!

OTOH, but for the movement led by Dr King, we wouldn't have people like
Colin Powell today.

You can`t beat mother nature in the long run. The nature of things is that zinc readily rots in the earth. Copper does not.

Look at the ground rod at your electric power meter carefully. Is it zinc, or copper?

Righto on the watering down technique. Thats what we used in the cemetery I had worked in for about 2 years. Had to still come back and refill/top off each grave a couple of times to keep the ground even. The mentioning in regards to cement was along the similar lines of why guy wire anchors and even the bases of the towers. This is assuming that there is now intent of moving the telephone pole.

enter fantasy mode
What I though would be a cool antenna support structure, provided the acreage was available, would be to have 2 of those huge metal high-tension electrical wire support structures. Think of all the dipoles, verticals and beams that could be affixed to those if you had the space and of course the money!!
exit fantasy mode

Interesting! Then the image that's in the ARRL antenna book is wrong
as well. I ignored the text of that web page, since it was opposite
of what the image showed, as well as what was in the ARRL book.

Should the shield be connected to the coil (after I remove the center
conductor), while I'm testing the resistance?

While I'm at it, any other pointers on this kind of antenna?

In 1882, Tesla began serious experiments with his rotating field (polyphase) a-c machines. Perhaps I should have said the rotating field was produced in a stator by phase rotation. The rotor chases the phases in the stator.

My real boo-boo was fat-fingering the keys and typing 1888 as the date. It was actually 1882 while Tesla was still in Paris that he started making polyphase machines that equalled or exceeded the efficiency of the d-c machines of the time.

I just purchased a High Sierra. While I think I'm going to be happy with it (it's not even installed yet), I was surprised by the warning that I'll need to replace the fingerstock annually (they say it might last 3 years, but that violates the warrantee), and you must disassemble the base and clean the brass (or likewise violate the warrantee).

So, just bear in mind screwdrivers are not maintenance-free.

I haven't really followed this thread but I must respond here.

There isn't a link to it on my home page but if you look at:

http://users.triconet.org/wesandlinda/w7uvr.jpg

you can see the old QSL card of my former neighbor and Elmer (gave me my Novice and Conditional exams), the late Lee Smith, W7UVR.

This is circa 1958-59 so the equipment dates from that era and was "state-of-the-art."

The vehicle was a 1955 Mercury with a 1956 Lincoln engine and truck springs and tires under the rear. (There was an extra leaf in the spring on the side where the HV power transformer resided)

Initially, the amplifier ran a 4-1000A, high level plate-modulated using push-pull-parallel 813's for modulators. Later it was converted to a linear for SSB.

The small beam on the top of the car could be elevated to a height of 30' using a pneumatic mast (visible in the middle photo inside the car). The beam was later replaced with a three-element tribander that was folded for travel using custom machined tubular hinges.

There were two whip antennas on the rear using motor-tuned edge-wound silver-plated inductors and vacuum variable capacitors. These were housed in the large Plexiglas boxes visible in the top photo. These were of course tunable from the driver's seat.

The generator in the photo is a 5KW Kohler, which was later replaced with a 15KW in a larger trailer. The equipment was also continually upgraded as the state of the art changed. (Even in these photos, the equipment is different)

So, 15KW mobile? I doubt it (corona problems) but not too farfetched if you put your mind and money to it.

I believe this mobile was on the cover of CQ magazine once but I never saw it. At some hamfests of the day they had mobile judging contests. When he pulled in, everyone else went home.

Ok, Thanks guys.

Two points,
1. Price is too high. Not sure I can do much about that,
a lot of labor in making this antenna.

2. Needs a balun, I was afraid of that.
Seems everyone agrees on it needing a balun.

Well I guess I have some studying to do. (about baluns)

Thanks for your help.

Source record: 149604

No! I believe, however, that the Hustler resonators, plus foldover mast do
cost around $200.
Some screwdrivers that I know of sell for around $179, but these are the
ones made of PVC
and "skinny" #16 wire. It's like anything else; you get what you pay for.
If you want a "basic"
screwdriver, you will STILL get more performance out of the SC than the
hamsticks--especially down on 40-80 meters--they SUCK big time down there.
If you want more performance, then my Carolina Cyclone is targeted to that
market and is still a bargain com-
pared to the "big" names!~

Hi Francesco,

This is the surprise I speak of: what they choose to argue about.
This is a standard ploy of school of fractal electromagnetics: ask the
wrong question and demand exact answers before defending the bogus
design. CFA and EH debates have shared this same prostitution of
argument.

So, that means you have to replace that "springy thingy" every year? Hmm,
that's interesting.
I never knew that. I make screwdrivers, too, but about the only thing I
tell people is that it
might need oiling after a couple years. If the drive shaft dries out, it
might start screeching or
making a howling sound. The fingerstock I use is VERY heavy duty (each
finger is 1/4" wide)
and extra springy. I replaced the fs on my own Cyclone antenna just
recently and the old
stuff had been on there for over 4 years. I know that fingerstock *can*
last a lot longer, but
it depends on how much one QSY's; some folks tend to hang around on the same
frequencies,
others jump around a lot.

The ideal situation is to have the "hot" part of the antenna above the roof;
i.e., loading coil and
whip. I've seen CB folks with those K40 base loaded antennas on the back
bumper of a van
(ouch), and I wonder how they get it to work at all.

> Best regards, Richard Harrison, KB6WZI

Still, there's the article I once read in a trade journal, it said
that companies are using galvanized because it lasts longer and is
cheaper. Note that I did not say that it lasts for ever.

My comparison was between copper clad steel and galvanized steel.

According to "Reference Data for Radio Engineers" (Howard Sams & Co,
2nd edition, 1977), page 4-14, in the galvanic series Zinc, Galvanized
steel, steel, iron, etc. are relatively close to each other. Copper
is farther away. So if a copper clad steel rod gets a scratch
galvanic corrosion action starts.

Besides I can go to Lowes and pick up an 8 ft galvanized steel pipe
for a few bucks. How much are copper clad ground rods now days?

Jason,

The tax deductions offset these other expenses. Trust me, you will be FAR better off in a house--even if you have to move--than you are in an apartment. Even if you start out with a modest frame 2 bedroom, you are STILL better off. An apartment is a money sinkhole; a house is an investment. Traditionally, home values always go UP. I know there is no guarantee of this, but it has held true. Example--my own house: I bought it in 1986 for $59,000. I did a few things to it (added a large deck and carport underneath, finished and waterproofed the basement, etc). Now the house is valued at $89,900. I owe less than $40,000. S0! That means that if I should sell it, I have an equity of almost $50,000! Had I rented an apartment all those years, I would have ZIP, 0, NADA! The younger you are when you buy real estate, the better off you are! Even if you start out with a small fixer-upper, you will MAKE money. The longer you stay in a house, the more equity you will build. After a couple years, or as you are forced to move, try to move up into a little more expensive house each time. Each time you will build equity. Yes, it is a bit more trouble to buy, sell, move, buy again. But overall, you will be MUCH better off. When tax time comes, and you take that deduction for $4-8000 in mortgage interest, you will appreciate the difference it makes.

AND, if you find a house that doesn't have those damned CC & Rs, you can have the radio shack you want AND all the dipoles/towers you want! My radio room is in a corner of my basement. There are 2 picture windows in that corner where I can look out on the back yard and the flowers, etc. I can watch the full moon rise (like it did last night) while relaxing down here...I LOVE my basement!

Best 73

Jerry

Here at the electrical wholesale, they sell 3x as many zinc dipped steel as copper coated steel. Why? zinc is less than 1/2 the price. ($4 vs $9 for an 8ft(?) rod)

No insults, but have you ever tried to convince an EE, or anyone with any
engineering degree
how something works in the REAL world? It's like talking to a brick wall!!
Example: I was
talking to an Electronics Engineer about the merits of certain types of
antennas over others in
a mobile environment. For a national group of people in search and rescue
work, he and his
engineer cohorts (the powers that be) are set on coupler/whip combinations
over antennas that
are resonant on every frequency (screwdrivers). Now I have no degree, hey,
I'm retired, but
I don't care how many EE degrees he holds, those coupler things are "smoke
and mirrors" gadgets that will fall on their faces down on 4 MHZ--they are
just as sucky as hamsticks on
low bands (below 20 meters). What he and his friends have done is evaluate
the couplers in
the "lab", found that they exhibit low SWR, good "phase angle", and decided
on that basis that
they will work fine! Hell, I can load up a 50 ohm resistor, but it won't
radiate worth a darn!
These guys feel that the people in the field are dumb, so they need a
push-button solution to
"tune" the antenna (there AIN'T no such thing as an antenna "tuner").
Nevermind that the traffic
might not get thru, never mind that vital information may be "stuck" inside
that "tuner/coupler"
gadget--just so the operator has convenience at the expense of reliability.
Bottom line according to the EEs? Throw money at it!

Sorry, I just had to vent--no insults meant.

Sylvan Butler wrote:
"Here at the electrical wholesale, they sell 3x as many zinc dipped steel as copper coated steel."

That is reasonable. The conductivity of zinc is good enough.

Zinc is fairly durable in most soils. After 50 years, I had to replaced the galvanized water pipe buried between the meter and the house. The original copper coated steel ground rod is likely good for at least another 50 years.

I don`t accept the assertion that galvanized outlasts copper. It ain`t so.

The life of ground rods and buried radials depends on the magnitude and
polarity of DC current flowing from electrode to soil.

So would a series 0.1 uF capacitor increase life expectancy. It would have
no effect at HF?

Why not save capacitors by using insulated rods and radials ?

"No insults, but have you ever tried to convince an EE with any
engineering degree how something works in the REAL world?"

Don`t you think the engineers at Boeing know exactly what they are doing and how the real world is challinging them? They are overcoming gravity.

How about the engineers that built the Golden Gate Bridge or Hoover dam? How about NASA? You think these only required technicians?

I related some of the Tesla story. Edison, a genius without education who got almost 1100 patents, couldn`t understand Tesla`s explanations of a-c power systems because he lacked sufficient background and didn`t want to believe they were real.

But Tesla`s fellow EEs in the New York AIEE Section, got it in an instant and lionized Tesla for his discoveries.

The more you know, the better off you are.

I've been told the PH of the soil makes a difference. Alkaline soil
the zinc will last longer but copper in acidic soil? Or was it the
other way around...

Reg:

By observing my wife's activities over the past --umpty ump-- years...

I have come to the conclusion that most women are far to intelligent to take on such menial and demeaning tasks as Engineering, especially when there are so many anxious men hanging around, who are willing to do those jobs for them!

On the other hand, the [few] women Engineers whom I have had the pleasure to call workmates have invariably stood head and shoulder above the average male Engineers within the same workgroups. I have found the same to be true among the YLs that I have encountered.

I wonder, does anyone here know? What are the statistics for the % of females in the ham population?

I personally believe that, for various reasons that could be elaborated ad infinitum, we [Society] need a great many more women Engineers amongst the ranks of Engineers.

Thoughts, comments...

Reg,
A 0.1 uf capacitor is much too large for that application,
you would actually do 'better' with a 0.001 uf.
An insulated ground rod will only work, as you suggest, if
the color of the insulation matches the color of the surrounding
soil.

I don't deny that EE's are a necessary thing, but have you ever tried to explain something to
one of them based on how their "idea" or product actually WORKED in practice? Many of the ones I dealt with simply won't listen to anyone who doesn't happen to have the same education
they do. Experience still counts for sumpin', at least to me.

Sylvan Butler wrote:
"I`ve been told the PH of the soil makes a difference. Alkaline soil the zinc will last longer but copper in acidic soil?"

Could be. Seems reasonable as carbon-zinc cells use an acid electrolyte. Alkaline cells use nikel and cadmium as electrodes.

If memory serves, soils where things grow are usually acidic.

I know that zinc is a donor to an acidic electrolyte because I remember the carbon-zinc primary battery cell. When it is discharged, the zinc case (zinc anode cylinder) has been largely consumed, and the leaking acid destroys your equipment. The carbon cathode is still intact. Yes, I know the cathode is positive and the anode is negative, but that is the way battery cells are described.

I don`t have any chemical reference that gives me comfort, and I`ve never kept up with chemistry, so I`m prone to error.

If there is DC flowing into or out of the ground, do we want to block it ?
I s'pose one could have an RF ground and a (disposable) DC ground.

Why should they?

2249. Has anyone homebrewed an antenna for an HT with an SMA connector?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-01 01:43:31 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0201311743.25bb5e9@posting.google.com>
Source record: 149533
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I have a Yaesu FT-50R HT transceiver, and I use the ADI/Premier RD-98 antenna with it when walking around.

The pros of the RD-98 antenna:
1. It is small enough to easily and quickly attach it to my radio.
2. It is dual-band (2m and 70 cm).
3. It has MUCH better performance than the rubber duck.
4. It is flexible enough to avoid breakage even when I bend it. This allows it to withstand MUCH rougher treatment than a rigid telescoping antenna can handle.

The cons of the RD-98 antenna:
1. It lacks a ground plane, and this causes the antenna to vastly underperform my J-Pole antenna and my mag-mount mobile antenna (assuming there is a ground plane). These other two antennas have their merits, but they aren't as convenient to use as the RD-98. (In case you are wondering, the J-pole has an SMA connector. I have a piece of coax with an SMA connector at one end for the radio and a PL-259 at the other end.)
2. I have to use a BNC-SMA adapter with it. This does add stress to the connector on the radio (but thankfully, nothing like the strain that a rigid telescoping antenna would cause). I know that there is now an SMA version of the antenna (which was not available when I first bought my RD-98), but a homebrew version would be cheaper AND be more conducive to the addition of radials.

Has anyone here homebrewed a 2m/70cm HT antenna with an SMA connector? I think QST had an article on this once, but the antenna used PL-259s or SO-239s.

The RF issues seem pretty easy. The vertical element can be a piece of metal wire that is 1/4 wavelength on 147 MHz, which would also be 3/4 wavelength on 441 MHz. This would be about 20 inches before making a slight adjustment for the velocity factor. I would then solder this to the inner part of the connector (I'm not sure what this is called, but it's analogous to the PL-259 at the end of a piece of coax). I would solder to the outer part of the connector one or more radials in order to provide a good ground plane. Then PRESTO! I have a REAL antenna that I can screw onto my Yaesu FT-50R.

The mechanical issues are much more challenging. What do I need at the feedpoint to hold the entire antenna together? What does it take to prevent moisture from leaking inside if I'm out in the rain? What does it take to keep the vertical element and the radials flexible enough (to avoid breaking the antenna or radio and make it more

compact for storage) and firm enough (so they retain their shape)?
16-guage solid wire, perhaps?

The RD-98 antenna seems to be made out of a flexible piece of wire
covered with a black plastic or rubber coating. There is plastic
cone-like object attached to the top of the BNC connector. I assume
it is there to mechanically shield the antenna feedpoint so it doesn't
fall apart.

Well I would. Its a sure sign electroysis is occurring. Cells last much
longer when the're left open circuit.

2251. Request for comment: Antenna Plan

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-01 01:52:44 UTC
From: Robert Fulton <robfult@carolina.rr.com>
Message-ID: <Mxm68.67245$a07.12730121@typhoon.southeast.rr.com>
Source record: 149541

After researching our by-laws, it appears that I CAN put antennas outside the house as long as the mast is not free standing. I have a shed approximately 50 + feet away from the house and would like comments on the following plan.

Starting from the TS2000x radio, I'm going to use a manual coax switch to switch between the two inputs needed on the radio. From the 2 position coax switch, it will go to an Ameritron RCS-4 switch which is a control cable-less system. One coax out the 2nd story, down next to the down spout, under the deck 50+ feet (using RG213/U) to the shed. Inside the shed it breaks out to the four connections.

Here's the antenna plan:

Isotron 40/80 on Ant 1
Isotron 20/15/10 on Ant 2
6M PAR antenna on Ant 3
Cushcraft 2m/440 on Ant 4

Since the TS2000 has separate 2m/440 inputs, I'll use a duplexer off one of the ANT1/2 connection of the two position switch.

Concerns:
Cable type appropriate?
1) I'm using the Coax switch to switch between radio ports instead of coax leads, would this be a problem?
2) I'm currently using all of the antennas with separate feeds INSIDE of my attic, will, in your opinion, the above plan provide better reception/performance?
3) The antennas will be mounted under the eaves of the shed (1 story) since the by-laws will not allow placement above the roof line. I'm sure there will be some attenuation on the side that the building is located, but would this be better (although lower than the attic (2 story house)) than current attic placement?

Thank you VERY much in advance for the time in reading and commenting!

73's, take care!

"---have you ever tried to explain something to one of them (an engineer) based on how their "idea" or product actually WORKED in practice?"

Yes I have. Engineers resist change, just as others do. I think Jerry may mistake apprehension for arrogance. Every design change is fraught with unintended consequences. This reluctance to change is an impediment to progress but has often proved prudent.

Best regards, Richard Harrison, KB5WZI

The problem is they are not doing it the DC way they are running large AC tube amps in mobiles.

They are running 6+/ 250 amp Leece Neville Alternators. They run 3 phase to step up transformers, and are able to put over 10,000 plate volts on these tubes (4cx10,000, 3cx3000a7, 3cx15,000,3-500z etc) albeit not for too many keys but they do achieve some massive watts, the corona is aleviated with a corona Ball on the top of the antenna.If you search the davemade web site he has a 1/2 wave base loaded mobile antenna, that has 2 giant fixed value 30kv capacitors at the bottom to load the thing. You know the watts are real when they key up and lite a 4' flourecent tube not attached to nothing but your hand and keep it lit as they walk away from the antenna for 50-100 feet. Makes a good field strength meter. But thats what they do for fun illegal or not. They spend tens of thousands on suburbans cruisin the USA going to Keydowns(Coffee Breaks).

Make a 2 element beam without the balun, use a gamma match. or no
match. look for the null off the back side. Much sharper than the peak
on the front side.

Reg:

In some of the more aggressive soils, broadcast stations are forced to impress a controlled level of DC on their radials and guy anchors (called cathodic protection) to make them survive longer. Buried pipelines, and especially metallic electrical conduits of any significance are also protected the same way, even though an insulating coating is applied first. One of the reasons why non-metallic conduit is preferred for many direct burial power applications. Your capacitor idea would work for an RF connection, but it might be difficult to find one which would survive in that location on a lightning protection ground. Better to control the polarity and magnitude of the DC. Corrosion protection handbooks detail the why and how. I never got very good at it, as I had several expert cathodic protection experts available, and always turned the requirements over to one or both of them.

Source record: 149545

When I power mine from a cheap power supply, the RF shuts
down the supply! So - maybe - RF gets into your supply and
causes the problem you see? (Somehow confusing the
processor in the tuner because of low voltage, and the
processor staying confused even though the voltage comes
back to normal when you go to receive mode.)

I haven't used my AT-11 enough to say it is definitely trouble
free. I got a 746 to replace my 745 shortly after I completed
the AT-11 build. The 746 internal tuner works great, so I have
no need for for the AT-11. For the short time I did use it (with
the same supply that powered the 745) I had no problems.

Richard, Jerry:

There is an old saying in Engineering, attributed mainly to aeronautical and civil fields, and in my observation, one that is very strongly espoused by *all* ECO [ECN] control boards/committees...

"No change is a small change!".

Hence the resistance to trying new things within the Engineering community.

As Richard has observed, following this approach is very often the prudent thing to do however, it does little to encourage inovation, and improvement.

How do you balance innovation, with security and safety?

Carefully or recklessly?

Is the status quo, "proven technology" or "obselete junk"?

That argument is, and has been, around for millenia.

Thoughts, comments?

Hi Jason,

I don't know if this is exactly what you are looking for, but I have homebrewed an antena for my TH-D7 that I regularly use for the outdoor events in my club and works reasonably well (much better than the supplied one):

(I hope my less than perfect english allows you to understand what I am explaining)

Just get a thin wire of flexible steel from a model toy shop; they use it in radio controlled planes and similar. Here they call it piano wire, because aparently it is similar to the wires used to make pianos. Well, cut it to about .27 wavelength (don't know why .27 instead of 1/4, but most references I found recomended it). Solder it to the inner pin of the SMA and put it in place. Fill the inside of

the SMA with two component epoxy or other heavy-duty glue. Put something at the other end of the wire to prevent it from harming you or others. You have it. You can bent it, allow rain to fall on it, ... Most important, if the wire is thin enought it acts as a "mechanincal fuse" for your SMA. It will bent before your SMA breaks.

Just another thing: Cut a 1/4 w. thin wire and put and 'eyelet?' on it, so that you can put it in the SMA before screwing the antenna on it. It will kind of work as a radial. It DOES make a difference with _any_ antena you are using!

Toni

My ARRL Handbook (1998) has some information on batteries and charging. It describes discharge of the carbon-zinc battery, mentions the Lithium, silver oxide, mercury, and rechargeables, but I see nothing on standard alkaline-manganese batteries such as those bearing a "copper top", or those that keep the "Energizer Bunny" going. I wish I knew something about these, which are really rechargeable primary batteries, I believe.

Best regards, Richard Harrison, KB5WZI

2269. Long Wire

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-01 10:53:22 UTC
From: Keith Powell <keith@keithg4jvx.force9.co.uk>

I am trying to locate an antenna which consists of a long wire with a matching unit at one end in a "black box". I thought it was/is called a Penetrator, but may be wrong as it is several years since I heard of it.

I have been on the web sites of all the UK dealers but can't find it listed. Does anyone please know if it is still available, and if so the URL of a site for it?

I need an antenna which is *completely* invisible, and from what I remember of this antenna, it should be suitable as it could presumably be fastened to the eaves of the house and the box placed inside the loft. Dummy drainpipes with verticals inside, etc, are out of the question. A wire antenna with no visible coax or twin balanced is the only solution in my case.

Any information on the Penetrator(?) will be very gratefully received.

Many thanks in anticipation.

So, your telling us that all engineers have no idea of how their products really work? Jerry, your posts really sound like some engineer burned you at one time or you unfortunately worked with a few bad engineers. Stereotyping all engineers or all technicians or all hams is ridiculous. There are some good engineers, good technicians and good hams. At the same time there are some poor engineers, poor technicians and poor hams. No one can judge the capabilities (practical or theoretical) of an engineer or a technician from their formal education. I know some engineers that are as or more practical than a lot of technicians. I also know some technicians that are better at designing antennas than some EEs. This varies with each individual regardless of their formal education.

An EE degree is evidence that an individual has some formal theoretical background (and practical if their fortunate) in a variety of subjects. It is a valuable foundation on which to build one's capabilities further. The EE won't really be a good engineer until he has several years of real world practical and theoretical experience behind him. A technician is in exactly the same boat. A technician won't be a good technician until he has several years of real world practical and theoretical experience behind him. Good engineers and good technicians will both have some level of practical and theoretical training.

Of course Steve is right on this, but the basis for the concern is factual.
Until the last few years, ECE departments did not put enough (or often any)
emphasis on design and hands on efforts, let alone 'real world', out-the-door
prototypes or products. That has changed dramatically in recent years, however,
and most ECE departments now have a strong emphasis on 'mainstreaming' their
students, and actively have industrial partners in that process.

I had a BB3 and the fingerstock kept breaking off. I love my High Sierra. If the stainless steel spring does wear out it takes just 5 minutes to replace. With the BB3, I had to ship it back to them three times. Stick with the HS. Their recommended maintenance is good advice. Do it, and the antenna will last for many years.

I'm thinking about trying to add two radials to my D7A. I'm using a
flexible 19" whip, so what I'm considering is just soldering a couple
pieces of piano wire to a washer that just fits over the SMA stud.

Experimentation with copper wire formed into an eyelet got noticeable
improvements with only one radial.

Source record: 149422

Al,

I'm not sure the commenters were considering the range of frequencies that your antenna can be used for. Compared to a simple antenna designed to be tuned and then fixed in the resulting configuration, the price is expensive. However, what you have put together is something that provides flexibility without the user expending a lot of time to design the antenna and put it together. There is always a tension between spending time and spending money, and where a ham comes down between the end points depends on what things give him the most enjoyment in the hobby - in this case design and construction or operating.

The questions in my mind are:
1) How large is the market for a direction finding antenna with that range of coverage? Most fox hunts take place on the ham bands, but on occasion a source of interference on another frequency needs to be found.
2) For the indended use, is the frequency selectivity produced by tuning the antenna necessary or could the same result be gotten with a log periodic antenna covering the same range and using the receiver for the frequency selectivity. Would a non tunable log periodic antenna be less expensive?
3) Is there a reason why even low-power transmitting is unsuitable? Being able to transmit even at a low power level would broaden the market.

I agree with the comments about a balun being necessary. If the antenna impedance is close to 50 ohms, a ferrite bead choke balun that covers the frequency range shouldn't be hard to construct, but will add to the cost.

You have come up with an interesting idea. I hope it works out as a product for you.

OK, So I have a presently broken TJ (BB3) screwdriver and would like to replace it with another screwdriver.

Is there a consensus in the newsgroup due to experience which is the best made, best performing screwdriver antenna. My needs are 6m to 80m, and rugged long lasting, minimum maintenance construction and good screwdriver performance.
It will be used with an FT847 in an RV.

While I have an ATAS100 in my car for my FT100 and it works quite well, I really want the 80m in the RV.

All comments and experiences are more than welcome.

I tend to agree about CB stuff in ham groups - but in THIS case, *I* won the bid on the item, and
intend to incorporate the antenna into some ham mobile antenna experimentation - in fact, I have
arranged to take *2* of them at the bid price of $19.99... How can you beat that price, as compared
to a Hamstick or Hustler that's built MUCH lighter and cheaper?

Mark:

I have done that in several locations.

That is... tuned radials by first laying them out on top of the ground and then trimming wire off the ends whilst monitoring the antenna current and the remote field strength.

For a stealth back yard inverted L with a few radials (6-7) tuning them that way takes the better part of a Saturday, i.e. it's about 6-8 beer job.

But the results I found were very worthwhile.

Seemed to make about 2- 3 S-units difference in my signal reports when compared to just cutting radials to 1/4 lambda free space wavelength.

For that location, using that particular stealth antenna, in an antenna restricted community, tuning the "hidden" radials by trimming for maximum radial currents made the difference between a workable ham setup and not being on the air.

Keith, why bother with coax and black boxes?

Just bring the long wire all the way into the shack. Make it a truly long wire. Keep as much of it as you can on the outside of the house. Use plastic insulated wire. If you have any, make use of PVC rain gutter brackets as supports.

It is quite obvious the arrangement you describe, some sort of transformer at the antenna end of the coax, radiates and receives just as much from the coax as it does from the length of wire the coax replaces.

You are merely feeding the same overall length of long wire at some distance along its length. The adverse effects being a change in the impedances presented to the transceiver and an increase in your credit card debt.

Furthermore, omitting the coax changes the impedance to values which are easier to match to the transceiver.

Without the coax the overall loss is lower. The number of bands available increases. Coax is restrictive.

And your invisibilty requirement will be more easily met. Keep everything except black antenna wire in the dry indoors.

Don't succumb to ignorant antenna salesmen's blurbs and old-wives' fairy tales about long-wire baluns. The money saved on coax and magic black boxes would be far better spent on a decent antenna tuner near to the transceiver. Better still - have fun making one for a fraction of the price. Crocodile clips are cheap enough.

Reg, do you have any idea how efficient a powdered iron core
transformer is on HF frequencies? Does the old 10:1 inductance
to resistive load rule-of-thumb work for powdered iron core
transformers with DC isolated primary/secondary?

The life of an electrode will depend on local soil composition to an
extent.

A very important factor is whether you encourage galvanic corrosion by
connecting dissimilar metallic electodes.

Whilst everyone is discussing the life of electrodes, I don't see
discussion of their performance. In my area, driven earth electrodes
perform relatively well (at power supply frequencies) as the ground is
substanitially clay. A small scale experiments over some years indicate
that a 25mm dia galvanised pipe electrode driven 2.4m into clay
consistently had an earth resistance of 200% to 300% (depending on
recent weather conditions) of a 12mm copper clad electrode nearby. This
would indicate that one requires a substantially larger earth system in
these conditions if lower cost galvanised steel pipe or star pickets
were used.

More importantly, your choice of electrode material (copper, copper clad
steel, galvanised steel, stainless, stainless clad steel are all readily
available and used for eathing here) should be influenced strongly by
other earthed metal that will be bonded to the system and which might
cause significant galvanic currents (eg premises water service, power
supply earth, power supply earthing system (eg MEN)). It is a mistake to
look at the earth electrode configuration of a cell base standing alone

on a remote rocky hill with HV feed and consider that it is a model for deployment in the suburbs with buried copper water services and MEN earth (though we could learn a lot from the overall earthing system design and implementation for lightning protection on cell sites).

Although in many installations, earth electrodes last a very long time, one should expect to make periodic inspections and measurements to ensure that they continue to be fully effective.

Is it the 11mtr band you mean, around the 27.555MHz usb.
these people have been using these frequencies for years, and no-one is
going to stop them. most r-hams including myself started of on 27.555, this
led to many of us becoming a r-ham.
have you got nothing better to do.

Hi,
I recently got the antenna coupler group RF-615 B Harris.
The mating connectors between the RF-615 B/C (Control Unit) and the RF-615 B/CU (Coupler Unit) are respectively 10-109828-21P and 10-109628-21S (37 pins each).
The instruction manual indicates the RF-613 cable for the fabrication of the multiconductor cable.
Who is selling the RF-613 cable?
Many thanks.

Take the radio back while you still can. I had to beg the dealer to take mine back. If your antenna has any gain at all you will have serious intermod problems on VHF. I had intermod so bad it broke squelch with the squelch at maximum setting. My unit had the blue, red, and yellow dots on the box indicating 3rd gen. If you don't live in the city it may not be so bad. Also listen to an active channel and scan with the other and you will hear a motorboat sound on the active one that is loud. Two known defects among others and mine was a very new model.

Sorry for the news,

Chris

Agreed. 10 years ago when I became a ham, 10 meters wasn't as
cluttered with lids who don't know the meaning of "operating split"
when it comes to chasing DX. As an ARRL member, I think it was a
shame the ARRL took the stance on the license restructuring. I've
seen posts on the DX Packetclusters from foreign stations saying "Boy
I bet the ARRL really must be proud of themselves". 10 meters used to
be a really fun band to be on, it still can be, but with lids who
don't know simple procedures and operating practices, radio
manufacturers might as well toss the license paperwork in the box
along with the rig. All in all, the ARRL is a good organization, but
any organization will make mistakes, big or small.

==========

If you are referring to the core material, generally, dust-iron cores are more lossy at low HF than HF ferrites. There's not much difference above 25 MHz. Depends on finesess of the iron powder.

Dust-iron is a much more linear material. To minimise harmonic and intermod distortion and for higher Q in power transformers it is to be preferred.

Trouble with dust iron is its low permeability. Roughly only 5% of HF grade ferrites. So many more turns of thinner wire are needed for a given inductance. Many more turns mean higher copper loss and greater parasitic capacitance which again means more loss.

I'm not sure what you mean by the 10 to 1 rule of thumb.

It is a rule of thumb that the reactance of a wideband transformer winding at the lowest working frequency should not be less than 4 or 5 times the load resistance across that winding. But that is to do with flatness of the frequency response at the lower frequencies and very little to do with efficiency.

As you know, when the transformer reactance is equal to the load resistance the frequency response is 3 dB down relative to mid-frequencies. The magnetising current equals load current. But the power dissipated in the transformer as a result of the severe 'mismatch' is far less than in the load and efficiency can remain quite high.

A wideband circuit designer is far more interested in frequency response (it may be of a hi-fi audio amp) than in efficiency.

...six $2 telescopic whip antennas with some pipe, some very nice clamps, and a bit of coax. The "design" would be on the accompanying charts - making use of the ruler cleverly hidden in the handle.

Obviously, the prime market is for biologists (etc.) tracking animal radio collars. THAT market will not notice the $139 price.

The ham market will be a bit tougher... ...we all know what telescopic whips actually cost. :-)

Rick:

You can't really judge Engineers, or any other trade or profession, by their behavior... that is far too subjective.

In the end it is only the "track record" that defines them.

You simply gotta define them by their deeds... not their words...

i.e. The acceptance by the marketplace of the products that they have designed and produced.

Nothing else really counts!

i.e. The guy that designed the 75A4 HF reciever was clearly a great Engineer, etc...

Dick,
The BB3 is mounted to a pole behind my stationary RV. The
mounting bolts on the pole broke in a windstorm and the pole with the
BB3 came crashing down.

The BB3 now has a loose something in it, (it rattles), and it doesn't
tune as well as it used to.

The failure is not the fault of the BB3, but the cost of sending it
back and forth etc.............plus repairs........

So if I cannot find a better one, I will have mine repaired, otherwise
I will invest the $$ in a new model from someone else.

2 sugestions.
Try two turns (More is no better) thru either a TV deflection
transformer
or one of the switch mode PSU output choke ferrites. Visit the local
TV doctor or the local PC shop for old 'puter powersupps.

I measured the isolation at 40m and it works fine with
2 turns (or 1, even!)

Just a thot.

Cheers.

A few months ago I took my BB3 to the Nott factory in Farmington, NM
to have it upgraded with the latest motor, drive mechanism, etc. It
cost me $50. That's essentially everything except the outer tube,
coil and cover. That's a lot less than a new one. Of course I was
going that way anyway, but shipping can't be all that much. They are
great people to deal with and will bend over backward to help you.

The transfer function amplitude plot of a Butterworth filter is smooth.

The transfer function amplitude plot of a Chebyshev filter contains ripples in the passband (if it is a bandpass filter) or the stopband (if it is a bandstop filter).

Am I correct that Chebyshev and Butterworth filters are classified by the shape of the plots of their transfer function amplitudes?

Is there a way to tell whether a given filter is a Chebyshev or Butterworth WITHOUT going to the trouble of finding the transfer function?

P.S. I am also looking for a job as an antenna, RF, or microwave engineer and would appreciate any leads. I will be targeting filter companies specifically (and presenting myself accordingly) once I thoroughly understand the basic ins-and-outs.

Hello,

I need some design advice on an antenna for 6 meters. I live in a 3rd floor apartment with about 7 by 12 ft of balcony space. I would like to build one, but would consider buying a used halo or loop if anyone would like to get rid of one. If you live in similar circumstances to me tell me what worked for you on the "magic band."

Thanks alot,

Chris N

Don,

Sounds like you may be the victim of low frequency vibration. All yagis
suffer from it to one degree on another. Usual cure is a length of rope
inserted inside the elements which damps the vibrations caused by
certain (low, I seem to recall) wind conditions. I've seen several
yagis (different manufacturers) start to rain parts at about the one
year mark, so yours is not unique. Oh, yes.... This seems to only
affect monobanders. Hy-Gain used to include the rope as part of the kit
in their monobanders. Must be that the traps on a normal tribander
somehow damp the vibrations.

Why waste a 259 for that? Use a cheapie SWR bridge.

So does Cauer and inverse Chebyshev, depending on order. And probably a
lot more.

> Am I correct that Chebyshev and Butterworth filters are classified by
> the shape of the plots of their transfer function amplitudes?
>

Yes. That is one of the ways they can be classified. There's also
classifying them by pole/zero locations,
classifying by phase response, classifying by the form of T(s). Changing
T(s) changes your
poles and zeroes, which changes your response. They are all different ways
of
looking at the same thing. You can even classify the order of a chebyshev
by counting number of ripples, for example.

> Is there a way to tell whether a given filter is a Chebyshev or
> Butterworth WITHOUT going to the trouble of finding the transfer
> function?
>

By looking at the magnitude response graph (if you are given it) as you
stated above. You want to look at the entire response
through all passbands, stopbands, and transition regions and use
characteristics from that.
Cauer-response filters have ripple in both pass band and stop band, for
example.

Or, if you have been _given_ an s-plane chart you can look at pole and zero
locations.
Butterworth filters' normalized poles lay on a unit circle, Chebyshev poles
lay on an ellipse

within that circle, Bessel poles lay outside the circle, etc. Since a butterworth and chebyshev
response provide more attenuation than needed in the stopband, they are regarded as inefficient.
By adding zeroes into the transfer function/ s-plane map, you spread the attenuation more evenly
throughout the passband and change the response accordingly, and therefore get an inverse chebyshev response.

Incidentally, butterworth, chebyshev, etc, are types of responses named after their respective
inventors. It does not describe the circuit used. You can make an active filter with a low-pass Butterworth
response using a Sallen-Key circuit, for example.

Of course, once you learn all this it was probably easier just to find the transfer function.. The best way to classify it without going through the trouble of finding the transfer function is have your friend do it.

> the vibrations...

Obvious invention - heavy mass (lead weight) in a damping agent (thick oil) mounted to the vibration nodes (halfway out, and either one of the thirds; or take the weighted average and make it ~0.4). Might take the form of a little 'film canister'-sized gadget clipped to the element (or hidden inside).

That'll be a dollar (the actual value of a typical "invention").

Actually, the are usually named after the polynomials used to privide the poles. I am not sure about the butterworth filter, but the chebyshev and bessel filters use those polynomials in the design of the filter. Their namesakes died well before filters with those names were ever used.

Bill

They don't run 12 volt dc systems. Alternators are capable of AC.

But for 15 KW, assuming about 50% conversion efficiency all down the
line, it would require somewhere between 400 and 500 horsepower to
the alternators.

Most common gensets are not capable of that kind of power output.

Don't blame the ARRL. While I have little use for the organization, it
was the screaming by Hams to get rid of the CW requirement that generated
the restructuring.

I personally believe that the restructuring that is being used is wrong.
Novice should be the entry level for HF, Tech for above 30 meters, with
Extra being the third class. Keep General if necessary, but there is no
real need for it.

I also believe that the written tests should be made more rigorous again.
They are trivial to pass, right now.

Of course we all have our differing opinions. As a 13 wpm General I feel slighted that a 5 wpm tech is to be shoved into my slot without ever having to pound a key. I dislike it, but I will live with it. It is for this same reason that I hesitate taking the written test for Extra. It seems that the Extras resent those of us that test "up" to Extra....after all, they earned their ticket the hard way and they see us newbie Extras as interlopers. They feel that I should not be an Extra since my 13 wpm did not meet the criteria.
Me? Heck. I don't care one way or the other.
You won't see me jumping forth to join the ARRL...I have better things to do with my time and money.
The old codgers who claim that it is the ARRL or nothing are fighting a losing battle. In light of the fact that only a third or less Ham Ops belong to the ARRL speaks volumes.
I like my hobby. I do NOT need the ARRL in any way, shape or form. They have done nothing for me and I doubt they will any time soon.

2339. Re: How do I classify filters WITHOUT looking at the transfer function?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-02 10:23:21 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C5BBE19.80B6A0F4@eznec.com>
Source record: 149476
Cross-posted to: rec.radio.amateur.antenna,alt.engineering.electrical,sci.electronics.design,sci.electronics.basics

Butterworth and Chebyshev filters are classified by the polynomials making up their Laplace transformed transfer functions.

The amplitude response of a Butterworth lowpass filter decreases monotonically from DC upward. This is, of course, only one of the characteristics of the response curve shape. The poles of a Butterworth are evenly spaced on a circle in the complex s plane. The amplitude response of a Chebyshev filter has ripple in the passband but not in the stopband, where it decreases monotonically. The passband ripples are equal in magnitude, and the number depends on the filter order. The pole locations are defined by a set of polynomials used for approximating functions, known as Chebyshev polynomials. They lie on what looks like an oval shape in the complex s plane. Bandpass filters have a response that looks like a lowpass and its reflection, all translated upward in frequency by an amount equal to the filter center frequency.

You'll never encounter a pure Butterworth or Chebyshev filter at high frequencies, although you'll often see a good approximation over a limited range of frequencies. Filters can be, and sometimes are, designed for characteristics lying between Butterworth and Chebyshev, or outside that range. They also sometimes include extra sections to adjust the phase response for a particular purpose.

The transfer function defines the filter type, so there's no way of knowing what one is by inspection, unless it's a matter of looking at the component values, then modeling or calculating to determine its response.

You have a very long way to go from asking this question to being seriously regarded as an engineer who's knowledgeable about filters. Filter design is a complex discipline that requires a lot of knowledge, creativity, and art. It's not something you can learn in a few weeks of asking questions and reading books. But if you're seriously interested in the theory behind filter design, I suggest beginning with a network synthesis text such as Van Valkenburg's _Introduction to Modern Network Synthesis_.

Last I checked, a horsepower was just under 750 watts (745.7 to be more precise). At 50% efficiency, 15 kW works out to 40 horsepower on my calculator.

Maybe they're just not makin' horses like they used to?

Entirely predictable, assuming you are just joining 50 ohm coax to the feed
point impedance of several thousand ohms.!
Feed it via a 100 foot stub of ladder-line or similar.
Or via a loop around a parallel-tuned circuit at the base.
Or wind it down to 130 feet

It is nothing to do with the wet.
You have rf currents on the outside of the coax between the ATU and the rig, Put a choke balun in it.
Disconnect the mains earth from the ATU.

If that doesn't work
then take 11 feet of wire and connect to the earth of the rig. Hang it down outside the house wall.

If that cures 15 m the add a 8 ft. piece for 10 and a 17 ft. piece for 20.

If that doesnt work come back and tell us the length of the ladder-line.

I've never heard of this, but thought I'd give it a shot.

We just had an ice storm, and all the trees are gone. So
I need a hole.

I hate digging, and thought of earth anchors. My soil is
the hardest clay I've ever seen. Would weld up neato
plate and put about a 30 foot tower on the thing, and
use about 4 big anchors, the kind that take 2 tons. No guys.

Probably a crazy idea, but I have an aversion to digging
deep holes. But I also have an aversion, I suspect, to
screwing those things in!

Please reply to jwodell@provide.net

hey jerry
in the effort it would take to screw in the anchors you could rent a
backhoe and dig you a tower base and be done with it and wouldnt have to
worry about frost heaving either

Jerry,
I'm not too sure 4 of the 'screw-in' anchors would
be enough to hold up a 30 foot tower. It would depend
on how much wind you get in your area. If you doubled
or tripled the number of anchors over a larger area,
then maybe. I understand the aversion to digging holes,
but dig one anyway. I think you'd be happier in the
long run.
'Doc

Many years ago I worked on a project that needed a very particular filter response to ensure optimum performance. Since I'm not a 'filter expert' (not even close) we took the problem to a local engineering outfit that had a real filter expert on staff.

We explained exactly what we wanted and the ins and outs (10 minutes). Then the filter expert turned around and turned on his PC. We were out the door in 30 minutes...

Jerry uses the MFJ259. I use a Daiwa SWR meter. I run the DC forward voltage
to the 'minus' input of an LM339 and the DC reflected voltage to the 'plus'
input of the LM339. The LM339 furnishes a ground to a power relay when the
reflected voltage is high and the power relay furnishes +12vdc to the
screwdriver motor control box. When the reflected voltage falls to a small
fraction of the forward voltage, the LM339 removes power from the relay
which drops out and removes +12vdc from the screwdriver motor. The only
catch is that the operator must know which way to start the screwdriver
motor moving.

Thanks for your responses (especially AH, Greatest Prime, and Roy). I definitely need to review my s-plane charts, as they reveal important patterns. I also know now that filters can have characteristics of more than one classification (such as both Butterworth and Chebyshev). I also have the answer to my original question: I cannot classify filters by inspection alone.

As you can easily tell, I wasn't born knowing filter theory like some individuals. So I have to start somewhere. However, I know that a decent grasp of filter principles is within my reach, because I graduated with a Bachelor's Degree in electrical engineering, and I am familiar with the prerequisite fundamentals (frequency response plots, electric circuit analysis, etc.). Also, ham radio has given me a perspective that no amount of coursework could have.

I hope everyone here is looking forward to an article called "How Ham Radio Made My Career".

Where do elliptic filters fit into this series? I suspect right in the middle, being an equi-ripple type thing, and presumably has a horrible phase response. All I remember from doing my MSc in Radio Comms 8 years ago was that they were a swine to design.

Another possible catch is that some antennas show multiple nulls for
SWR. How do you know you are on the right one? Perhaps screwdriver
antennas are less susceptible, but my various dipoles at home have a
number of minimums in the HF and low VHF range.

Again I am returning from my Saturday ham club breakfast with engineers.
Again I am repeating survey results on Jason`s questions.

This week there was another confirmation that hams usually don`t make it
to graduation as EEs.

Jason`s question about filter characteristics is answered by, job
interviewers rarely ask such questions. Interviewers assume technical
competence from the record. The interviewer wants to know if the job
applicant is someone the company can live with comfortably. Is he a
pleasant dependable person?

There was an exception. If times are tough, the hiring company may be
very selective. They may only look at highest honor graduates. If there
are plenty of these, some may actually dig into technical preparation.
One of our engineers applied to Shell Oil in 1950 and was given a
written test. That is a definite exception and not the rule.

If I were asked for an additional way to classify filters I`d say,
balanced and unbalanced.

Best regards, Richard Harrison, KB5WZI

The similar problem that screwdriver antennas have is confusing
3/4WL with 1/4WL. For instance, when moving from 80m to 10m,
the circuit might find the 3/4WL position. A toggle switch
that temporarily bypasses the relay is a solution. The
operator knows approximately how much of the coil needs to
be exposed for each band.

Hello, Bob AD3K
Thanks for your comments.

I would like to make a comment about price.

We also sell a 2 meter 1/4 wave ground plane for $29.
Any Ham should be able to make an antenna that
would work just as well for less than $2.
(SO239 4 hole connector & some Brass wire)
Why do we sell so many of them ?

As for the Adjustable DF Antenna, I doubt very much
if we will sell any to Hams.
This project was originally started because of requests
from the FAA & Search & Rescue.

So far I have a lot time, money & equipment invested in
making these Antennas, and it looks like it's got a ways
to go.
Anyone want to submit a bid for making the baluns for
this antenna ?

By inspecting WHAT? You CAN classify them by inspecting the frequency
response curves. It is rather easy to do that for Butterworth, Bessel
and Chebyshev types, but it is difficult for some other types.

Fine. The wind will try to overturn your tower. You need to pick the maximum wind speed to be tolerated and sum the loads times their distances from the fulcrum that the appurtenances and the tower make. The forces on the tower will act like a claw-hammer pulling a nail. You need to make a summation of the moments. The moment resisting the overturn equals equals the overturning moment, as long as the system is in equilibrium as it remains until something gives.

What I did was to carefully tune my screwdriver with an MFJ-259 then
mark those spots with plastic labels (P-Touch). I can see the tapes
in my side mirror so I know if the antenna is trying to find one of
the other null points.

I have had a Cushcraft A50-5s 5 element 6 meter antenna installed on a 40' tower for about 12-14 months...yesterday I noticed the rear director had broken off and was laying on the ground. There were no signs of bending...looks like metal fatige. It did not snap at the mounting bolt location, but rather about a 1/2" past it.
Has anyone else had this type of problem with Cushcraft antennas???
Has Cushcrafts quality dipped to this level??

I called Cushcraft and presented the problem...the reponse from the Tech Support Dept was..."we have not seen any problems"

You didn't say what kind of tower you were wanting to put up. Is it designed to be self supporting? If not, it won't work more than short term. The tower will stay up quite awhile, but the sections will wear out the holes where they go together over time.

Slightly off topic, but loosely related to your question...

Personal experiences:

I took over maintenance on a site where Rohn 55 was used to support a television translator antenna system. There are three yagis on a mast at the top of the unguyed 50+ foot tower. Ten years ago, when I first got the site, I climbed the tower with ease. I noted some sections were loose and wobbled a bit, making me nervous. The owner didn't want to do anything about it. The site had been there since the late 60s, but I'm not sure how long that particular tower had been up. Last year, I told them I wouldn't climb it again until it was guyed. We had the power company put in three screw anchors and guyed it with one set of guys a few feet below the top. It will last a long time that way. Winds at that site would easily reach 60-75MPH.

At another site, there is a very light duty self supporting 40' tower (tapered). It has two wire dipole-like HF antennas on it and one 15' vhf omni directional gain antenna on top. The tower is sitting on 3 SMALL screw-in anchors. The disks on the anchors are about 2.5-3" diameter, and the length is less than two feet. This was meant to be a temporary installation when it was put in almost twelve years ago, and it is still there. There are three very light ropes on it to back up the anchors, but they rarely come into play. Some help is provided by the dipoles.

My point is, it may not be good practice or good engineering, but you can get by with a lot of things if you are willing to take the risk and are aware that it won't last forever. By the way, the second site is next to my house. That same tower held my TH-4, and later my KT-34XA for several years at another location. It did pull out the anchors during one VERY strong wind with the XA on top of it. The dipoles were anchored well enough that it held up at a very odd angle until I woke up

and discovered it. It had rained a lot and the ground got soggy. I wouldn't think of doing that now. Hence, the newer tower shown on my "tower" web page.

Gary

Amateur Radio Newsline™ Report 1277 – February 1, 2002

Amateur Radio Newsline report number 1277 with a release date of Friday, February 1st, 2002 to follow in 5-4-3-2-1.

The following is a Q-S-T.

The President of the United States speaks to hams in Florida and is ham radio seeing a second Solar Max? These stoies are first on amateur Radio Newsline report number 1277 coming your way right now.

(Billboard Cart Here)

**

BREAKING NEWS: PRESIDENT BUSH COMES TO HAM RADIO

The President of the United States has come to ham radio. Bill Burnett, KT4SB, has the details:

--

President George W. Bush has taken to the ham radio airwaves. This, to thank the Florida Amateur Radio community for being ready to serve the public when it is needed.

The President’s comments were made during a stopover the morning of January 31st at the Volusia County Fire Services and Training Center near Daytona. Around 9:15 AM Eastern Time, President Bush checked in to the Northern Florida Amateur Radio Emergency Service Net on 3.950 MHz using a portable station set up John Schmidt, AF4PU. Then the President made these remarks to the 40 or so stations listening to the net:

--

President George W. Bush:

"I want to thank all the volunteers who help make sure that Florida is prepared for any kind of emergency. I also want to assure you that your Federal government is doing everything we can to make sure that there is not an emergency--starting with unleashing the mighty U.S. military overseas to bring evil ones to justice. But should there be a need for a response, I want to thank you all for helping our communities be prepared. And finally, I want to tell you--we are lucky to be Americans and may God continue to bless this great land of ours. Thank you very much."

--

Needless to say the net members were delighted to have the President of the United States address them. More important, hams nationwide can now be sure that President Bush knows that Amateur Radio operators are ready to serve whenever he, and the nation, needs to call on them for help.

In Miami, I'm Bill Burnett, KT4SB, reporting for the Amateur Radio Newsline.

**

HAM RADIO SCIENCE: TWO SOLAR MAXIMUMS THIS SEASON

In case you are wondering why the current solar cycle is still providing such amazing VHF and UHF DX, one researcher may have the answer. He says that the current cycle appears to be having a second peak and that this is really not very unusual. Henry Feinberg, K2SSQ, looks at the scientist and his latest data.

--

The most recent and ongoing Solar Maximum -- or Solar Max -- theoretically crested in mid-2000. Sunspot counts were higher than they had been in 10 years, and solar activity was intense. One remarkable eruption on July 14, 2000 caused brilliant auroras as far south as Texas. But after that, sunspot counts slowly declined and the Sun was relatively quiet for month-long stretches. Most scientists said that the Solar Max was over. But was it?

Now, as 2002 unfolds, the National Aeronautics and Space Administrations solar foorecasters say that it looks as if the Solar Max is back with us again. The Sun is again peppered with spots, eruptions are frequent and hams notice that the VHF DX keeps rolling in.

Why is this happening? Well David Hathaway, a solar physicist at the NASA Marshall Space Flight Center in Huntsville Alabama has one theory. Hathaway says that the current solar cycle appears to be double-peaked, and the second peak has arrived.

--
Hathaway Audio Here
In-Q: We have seen other cycles...
Out-Q: ...define this maximum
--

Scientists track solar cycles by counting sunspots and Hathaway is an expert forecaster of sunspot numbers. He says that sunspot counts peaked in 2000 some months earlier than we expected. He says that the subsequent dip toward solar minimum seemed premature and before long, sunspot counts reversed course and began to climb toward a second maximum that now appears to be only a few percent smaller than the first.

--
Hathaway Audio Here
In-Q: Its a bigger than average...
Out-Q: ...smaler than 19, 21 and 22.
--

Hathaway notes that there is a widespread misconception that solar activity varies every eleven years like a pure sinusoidal wave. It isn't. He says that solar activity is chaotic and there can be more than one peak in any given period. Translated for ham radio: Enjoy the VHF DX while you can.

For the Amateur Radio Newsline, Henry Feinberg, K2SSQ.

--

Hathaway says that the Solar Max eleven years ago was much the same as this one. The first peak arrived in mid-1989 followed by a smaller maximum in early 1991. And if you are interested in hearing more about this interesting phenomena from David Hathaway its as easy as taking your web browser over to www.rainreport.com. Or you can call on the phone to area code 847-827-7246. (NASA, RAIN)

**

HAM RADIO IN SPACE: HF ANTENNA INSTALLED ON ISS

High Frequency ham radio operations from the International Space Station could be on the not to distant horizon. This, after a successful space walk on January 25th to install another antenna on the orbiting outpost. Amateur Radio Newsline's Roy Neal, K-6-D-U-E, has the details.

--

The spacewalkers have had another good day in space. On Friday the 25th of January, Cosmonaut Yuri Onufrienko, RK3DUO and Astronaut Dan Bursch, KD5PNU, successfully mounted a second ham radio antenna near a docking port amidships on the International Space Station. It is made of flexible tape and is similar to but longer than another antenna installed on January 14th. That one tunes both VHF and UHF frequencies. The new antenna will tune HF frequencies.

ARISS Board Chairman Fran Bauer, KA3HDO, says it definitely will work on ten meters and may even be made to work on 15 and 20 meters. BUT right now there is no gear on board to handle those frequencies. Experiments using the lower frequencies are on the list of futures for ARISS but no timetable has been assigned to design and build them.

Owen Garriott, W5LFL, the first man to operate ham equipment in space, once prophesied that a five watt transmitter in orbit might well be heard simultaneously world wide. The great number of hams with good stations on the lower frequencies also makes them enticing to ARISS. It's a safe bet that serious consideration now is being given to expedite such a project. Once a station is sent up, the antenna will be waiting.

The new antenna is the second of four to be installed on board the space station. No timetable has been announced for the final installation. All of

these amateur antennas were built by Italy, tested and qualified in the US, to fit ports built by Russia, as befits the international nature of the ISS.

For the Amateur Radio Newsline, Roy Neal, K6DUE

--

Installation of the 2.5-meter long flexible tape antenna involved not only the mechanical deployment but routing cables and establishing the R-F connection as well. (ARISS)

**

HAM RADIO IN SPACE: THAT ANNOYING SATELLITE IS OFF 2 METERS

An annoying mystery satellite transmitting AFSK, frequency modulated Morse on 144.100 MHz for several days has been identified. It turned out to be a signal from the MAROC-TUBSAT satellite. This is an Earth-sensing spacecraft owned by a Moroccan government agency called he Royal Center for Remote Sensing. It was placed into a polar orbit by a Russian launcher on December 10, 2001.

As soon as he learned of the interference to amateur operations, Professor Udo Renner of the Center had the 144.100 MHz transmitter turned off. He then notified AMSAT Germany that TUBSAT was no longer on two meters.

But TUBSAT also has a downlink at 436.075 MHz. This system is only busy over North Africa and Europe and only when the control stations in Rabat and Berlin are activated. It has not been heard elsewhere in the world. (AMSAT-NA)

**

SPECTRUM PRESERVATION: ARRL SAYS IT WILL FIGHT TO KEEP RFID OFF 70 CM

The ARRL says that it will go all the way to protect the 70 centimeter ham band from a threat brought by commercial interests. At issue is a plan from SAVI Technology and already tentatively agreed to by the FCC to deploy unlicensed transient R-F identification tag transmitters operating between 425 and 435 MHz. These tags run at much higher field strengths and duty cycles than Part 15 rules now permit.

According to a League bulletin issued on January 29th, ARRL officials have already met with members of the FCC staff as part of the League's effort to stave off a band threat. The bulletin says that General Counsel Chris Imlay, W3KD, and ARRL Technical Relations Manager Paul Rinaldo, W4RI, delivered an ex parte presentation to FCC Office of Engineering and Technology staffers January

14th outlining the opposition of the ham radio community. (ARRL)

**

FCC: CHAIRMAN POWELL HOME AFTER HOSPITAL TESTS

Federal Communications Commission Chairman Michael Powell was discharged from the hospital on Friday January 25th. This, after a two-night stay in the to undergo tests because of a lingering stomach bug.

Stomach discomfort caused him to cancel appearances at the Consumer Electronics Show in Las Vegas on January 8th and again at the annual conference of the National Association of Television Program Executives on Wednesday January 23rd. Doctors advised precautionary tests that required overnight stays at Walter Reed Army Medical Center in suburban Washington. (Published news reports)

**

ENFORCEMENT: THAT SONG WAS NOT AS BAD AS WE THOUGHT

The Federal Communications Commission has dropped an indecency fine against a Colorado radio station. KKMG FM of Colorado Springs had been fined seven-thousand dollars for airing the edited version of Eminem's "The Real Slim Shady." This, after a listener wrote the regulatory agency to complain.

At the time the fine was issued federal regulators said the edited version still included some expletives and references to violence and graphic sex. But the FCC now says it has reconsidered. It now says that the lyrics in the edited version didn't violate its rules by being "patently offensive." (FCC)

**

RESCUE RADIO: BRAZIL RADIO OPERATORS HELP IN POWER OUTAGE CRISIS

A major electricity blackout hit at least five Brazilian states on January 21st, and it was hobby radio enthusiasts that let people know about it.

The blackout, which began at 1:30 p.m., hit hardest in the industrial southeast and the major cities of Sao Paulo, Belo Horizonte, Rio De Janeiro, Goiania, Vitoria and the capital, Brasilia.

According to news reports, Brazil’s National Energy Agency blamed the outage on transmission line failures. The same news report credited Brazilian hobby radio operators as informing authorities that subways in Rio De Janero and Sao Paulo were halted and that traffic lights were out snarling commuters in several areas.

The outage was caused by a failure at the Itaipu hydroelectric station in southwestern Brazil. A power-line failure caused thirteen of the dam's eighteen turbines to stop, cutting off nearly 20 percent of the country's energy. Power was restored about three hours later. The news story did not identify the radio operators as being hams. (Various shortwave news reports)

**

RESCUE RADIO: NEW INTER-JURISDICTION RADIO SYSTEMS BEING INTRODUCED

Santa Clara County California, police, fire and emergency medical personnel have never been able to communicate with one another at the scene of a major disaster. This is because each agency uses a separate radio system. That is expected to change this year.

Santa Clara County will be leading the nation in using new digital radio technology to solve the inter-agency communications problem. The new system will allow up to eighteen participating jurisdictions in any county to talk to one another instantly.

By way of example, once the system is up and running, officers involved in one of California's famed high-speed car chase will be able to talk directly to police in the neighboring jurisdiction as the suspect approaches that town. They won't have to switch channels or go through dispatch centers. This means less time wasted and the probability that lives will be saved.

While Santa Clara county is at the head of the pack in adopting this new digital communications technology, the same news reports say that and Washington, D-C is not far behind. (Cal-State Info.)

**

PUBLIC RELATIONS: A CHEAP SATELLITE

A Cheap Satellite is the name of an Associated Press item that highlighted the work of the faculty and students at the United States Naval Academy in the development and launch of the P C Sat ham radio satellite. The story tells how the twenty-five pound bird was built using off the shelf products including a tape measure for its antenna and rechargeable double A cell batteries for power.

The story was written by Tom Stuckey and moved on the wire on Wednesday January 23rd. It noted that PCSat, was the 44th amateur satellite put in orbit. It is one of more than a dozen built by university students around the world. (VHF Reflector)

**

CONVENTIONS & HAMFESTS: ORLANDO HAMCATION WEAK SIGNAL FORUM

The Orlando HamCation will host its first ever Weak Signal VHF and UHF forum. Beginning at 2 p.m. on Saturday Ferbruary 9th, the one hour session will be moderated by N2CEI, of Down East Microwave. Also, Tom Haddon, K5VH, will be on hand to motivate more Florida hams to become active on the Microwave bands.

If you are in the Orlando Florida area on February 8th to the 10th drop in on the Orlando Hamcation. For more details and or advance reservations, go to oarc.org/hamcat.html on the World Wide Web (W2BZY)

**

CONVENTIONS & HAMFESTS: DATE CHANGE FOR RADIOFEST 2002

Brian Broggie, W6FVI, asks that we pass along a date change for RadioFest 2002 sponsored by the Naval Post Graduate School Amateur Radio Club in Monterey California. The new date is February 23rd. More information is in cyberspace at k6ly.org/radiofest. (W6FVI)

HAM RADIO SCHOLARSHIPS: THE DARA SCHOLARSHIPS

The Dayton Amateur Radio Association is one of three ham radio organizations seeking nominations for its scholarship program for the 2002-2003 academic year. According to DARA, applicants must be graduating high school seniors in 2002 and hold any class of an FCC issued mateur Radio license. The scholarship awards run up to $2000, as determined by the scholarship committee. Money must be used toward tuition at an institution of higher education.

To obtain an application, send a self-addressed, stamped envelope to the Dayton Amateur Radio Association Scholarship Program, 9873 Lower Valley Pike, Medway, Ohio 45341. You can also obtain an application by e-mail to n8emo1@msn.com. Completed applications must be postmarked no latter than June 1st to be eligible for this years scholarship program. (DARA)

**

HAM RADIO SCHOLARSHIPS: THE FOUNDATION FOR AMATEUR RADIO

Another organization offering scholarships to hams id the Foundation For Amateur Radio. The Washington, D.C. area group will administer sixty-two scholarships for the academic year running from 2002 through 2003. Licensed Radio Amateurs may compete for these awards if they plan to pursue a full-time course of studies beyond high school and are enrolled in or have been accepted for enrollment at an accredited university, college or technical school. The awards range from $500 to $2500 with preference given in some cases to residents of specified geographical areas or the pursuit of certain study programs. Additional information and an application form may be requested by letter or QSL card to the FAR Scholarships, Post Office Box 831, Riverdale, Maryland, 20738. (Foundation For Amateur Radio)

INTERNATIONAL - SOUTH AFRICA: SA RADIO AMATEURS OF THE YEAR NAMED

Turning to international news, South Africa is honoring two of its own as that nations Radio Amateurs of the Year. Q-News Graham Kemp, VK4BB, brings us the details:

--
The South African Amateur Radio Development Trust have announced the winners of the 2001 Siemens Radio Amateur of the Year Award. This award is made annually to a Radio Amateur who has made a major contribution to the Amateur Service either on a technical or development basis in ZS land.

The award has been bestowed jointly on Bradley Phillips, ZS5BP, and Garth Wilson, ZR6CY. ZS5BP for his work on the introduction of Iphone and the development of the Internet Radio Linked project. ZR6CY for his continuous efforts to develop communication skills amongst the youth. He has to date presented no less than 80 camps for Voortrekkers to learn the Morse code and basic communication skills.

For Q-News Australia, I'm Graham Kemp, VK4BB, reporting for the Amateur Radio Newsline.

--

This award is considered as South Africa's equivalent to the Dayton awards presented here in the United States. (SARL News, Q-News)

**
INTERNATIONAL - UK: KENWOOD TROPHY AWARDED TO G3XWH

Meantime, over in the U-K, Richard Horton, G3XWH, who chaired the RSGB's Future Licensing and Examination Forum has been awarded the Kenwood Trophy. This, for his significant contribution to training and development in amateur radio.

Horton recently retired from the Radio Society of Great Britain's Board where he was responsible for amateur radio development. His committee was responsible for much of the work that went into the creation of the new U-K Foundation Class license. (GB2RS)

**
DX

In DX, DJ4KW and DK9GG are currently active from Belize as V31YN and V31GW, respectively, through early February. Activity is on CW, RTTY and PSK 31. (RSGB)

And IN3QBR will be active from Vientiane as XW3QBR until the 31st of July. He will be joined, from the 20th of April until the 10th of May by IN3ZNR operating as XW3ZNR. (OPDX)

And R1ANF began operations as CE9 slash R1ANF on the 29th of December from a Chilean base in the South Shetland Islands. He is active on 10 to 28MHz with 100 watts to an R6000 vertical. For all three QSL as directed on the air. (RSGB)

**
THAT FINAL ITEM: CELEBRATING THE LIFE OF ED CLEGG W2LOY

And finally this week, if you were on the VHF bands in the 50's, 60's and 70's then the name Clegg Labs touched your ham radio operations. And as we hear in

this report, the family of the man behind the gear is inviting you to help celebrate his life.

--

Even if you did not own any Clegg gear, the chances are that you talked to someone on the air who did. Whether it was the top of the line Interceptor receiver and Zeus transmitter or the entry level 99'er transceiver, it was easy to spot a Clegg signal by its almost overpowering modulation that seemed just right for the R-F carrier it was on.

Almost every product that carried the Clegg label was designed by the company's founder Edward T. Clegg, W2LOY. When he moved the company to Pennsylvania in the 1970's, Ed took the call W3LOY. Likewise, after retiring to Ohio he traded the 3 for an 8, but kept the famed L-O-Y suffix.

And regardless of the call area, Ed Clegg was first and foremost a communications designer well ahead of his time. Even more important, he was a positive influence on just about everyone with whom he came in contact.

Ed Clegg left us last September at age 80. Now, his wife Martie will be hosting a gathering in March near the Clegg home in Lancaster Ohio. The purpose is to celebrate the life of Edward T. Clegg. And they are asking you to help.

Martie, her daughter Linda and Linda's husband Rob MacGuffie, K2HZN, are asking anyone who knew Ed to share in the celebration. They know that most of you won't be able to be in Lancaster Ohio on March 30th. But some of you do have memories, stories, photos and other Ed Clegg memorabilia that would help to make this day even more unforgettable.

If you have something to share, please contact Linda and Rob before the end of February. Their address is 70 Province Road, Gilmanton New Hampshire with a zipcode of 03237. Rob's cyperspace address is K2HZN@yahooo.com.

For the Amateur Radio Newsline, I’m Cathy Anno, KB0FDU.

--

By the way, a number of us here at the Amateur Radio Newsline began our ham radio careers using gear designed by Ed Clegg. In fact, our producer Bill Pasternak, WA6ITF, got to know Ed while Bill was still a teenager operating A-M on the 6 meter band. (Clegg family)

Jason:

To paraphrase Marvin Minsky... "An ounce of perspective is worth 100 points of IQ".

If you really wanna be a filter expert, ya gotta look into the "Characteristic Function" of filters.
The characteristic function through "Feldtkeller's Equation" completely classifies and characterizes
almost all practical filters. How do I find out about the "characteristic function" you ask?

Below here's a few quick references on practical filter design, just to get you started...

Shoudn't take you more than a weekend or so to read em all and them summarize them back to
us here on the NG so that we can all become experts as well.

The classic treatise on the whole design methodology of filters is:

1. Rudy Saal, and E. Ulbrich, "On the Design of Filters by Synthesis", IRE Trans., Vol CT-5, pp. 284-327, Dec. 1958.

A neat round up of the most amazing history of this field by one of the "greats" is:

2. Anatoly I. Zverev, "The Golden Anniversary of Electric Wave Filters", IEEE Spectrum, Vol. 3, pp. 129 - 131, March 1966.

Zverev also has published an extensive tabulation of filters by their element values:

3. Anatoly I. Zverev, "Handbook of Filter Synthesis", John Wiley, NewYork, 1967.

For an extensive tabulation of all kinds of filters by their mathematical parameters, poles
and zeros, Amax, Amin, type, etc... complete with graphs/nomographs and other design aids.

4. Erich Christian and Egon Eisenmann, "Filter Design Tables and Graphs", John Wiley, New York, 1988.

For devilishly simple explicit formulae for elements of LC ladder filters, and an amazing
background on their derivation, by such experts as Bennett, Saraga,

Takahashi, et al.
See Weinberg below, pp. 651-659, there is *amazing* stuff in there for a "wanna be"
filter design expert.

As George Strait says in that song, "Write this down"... heh, heh... put those explicit
formulae on one of your wife's recipe cards and keep them in your shirt pocket, for
cribbing during the job interview tests!

5. Louis Weinberg, "Network Analysis and Synthesis", McGraw-Hill, 1962.

For a lot of very high level practical stuff on filter design, including complete analysis
programs in Fortran up to and including filters with "imaginary resistors" and discussions
of various transformations to get "nice" element value ranges, some neat stuff on
crystal filters, and more tabulations see...

6. DeVerl S. Humphreys, "The Analyisis, Design and Synthesis of Electrical Filters", Prentice-Hall, 1970.

And last but not least for the "best" practical explanation of all, "heh, heh", see...

7. Adel S. Sedra, and Peter O. Brackett, "Filter Theory and Design: Active and Passive", Matrix Publishers, Champaign, 1978.

Jason, my boy...

Enjoy! Shouldn't take you more than a fortnight to master those few references.

Hope to see you "active" in the filter design field in a couple of more years...

--Peter K1PO

I've been a ham since 1968 and had my Extra since '74, so using your terminology, I took the tests "the hard way". I resent no one who enters our hobby no matter how he or she took any tests. And I do not consider a "newbie Extra" (your terminology) as an "interloper". Please don't wrongly judge many of us who have been in the hobby most of our lives and are happy to see ham radio thrive. Your note indicates that you are the one who is biased. We all share a common hobby, but sometimes I wonder.....

John,
I'm about 2-3 years behind you in Novice and Extra. When I got my Extra
they were doing the multiple choice code test at a Hamfest instead of
solid-copy under the watchful eye of the FCC-marm in the Atlanta office,
a 5 hour drive away (or 5 days if you had to walk barefoot in the snow
carrying a load of firewood). The written test had been 'watered down'
to where it was easier than my Advanced. You'll probably recall that
that Extra was considered 'cheapened' at the time. And there was a time
when I wouldn't be caught dead with one of those newbie calls like I
have now.
Yes indeed, these little arguments fade with time. I don't think ham
radio is in danger of being overrun by people who aren't interested and
just get a license or upgrade because they are bored that day.

Yeah that's fine if all ya wanna do is be a lonely bachelor for the rest of
your life...

But if ya wanna get married and have a family, gotta go for that "Masters".

Bzzzt. Although the ARRL is a lobbying force for hams, it is also a
lobbying force utilized by equip mfrs who would like to have a larger
market. The non-hams out there whittling toothpicks and cursing ham
radio because of the code requirement are not directly represented.
I don't think most of their members as licensed hams are screaming for a
reduction in standards.
Could be wrong. Follow the money...it says Icom/Yaesu/Kenwood/etc.

I saw your post on rrs and I suspect that this request references that.
Apart from building a simple dipole or ground plane and getting it well
out into the open, maybe a small beam is in order.
E-skip on this band often arrives at high angles and a beam is not
always necessarily better than a dipole...but won't be any worse. The 5
or 6 db you gain with say a 3-el beam may help in some cases when the
angle is low.
From my experience with TV-FM DXing, best advice is to get the antenna
out into the clear and as high as possible. Any gain is usually
irrelevant when the band is wide open.

What ant are you using now copying Calif on 42 Mhz?

That is a good source for DX spots AA7YA....and just recently now
DX-Central has added some nice new - free - DX spotting features.

Once you setup a free account you can then also setup DX spot filters
by band and mode and also by originating country. DX-Central is the only
web browser based DX spot service that has filters.

Also they offer free email notification of DX spots of any prefix(s)
you want to be alerted about. Now I don't depend on the email spots for
my first level of DX info but it is a very good auxiliary source for
spots and for the chance to snag a new one.

It costs nothing to setup the DX-Central account....email address and
password and you're ready to go!

2395. Newbie question: So why is my coax feed line radiating?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-03 03:12:30 UTC
From: cprstn54zz@att.net
Message-ID: <3c5ca87b.14931484@news-server.optonline.net>
Source record: 149381

Is it because the center conductor induces a current in the sheathing,
or because the sheathing picks up RF from the dipole antenna?

Why put the coil of coax (choke) near the antenna feed? Why not at
the radio? Why not at both places?

I have 100 ft of RG-8X between my 10 meter dipole and the radio. I
have coiled up the coax as per the ARRL Handbook (7 turns in a 4"
diameter circle) at the antenna. My feed line is still radiating RF
big time, as are my microphone and radio chassis. My SWR is 1.10. Do
I need a 1:1 balun? What else can I do? Should I care?

good day on the news,

I own a 16 elements colinear antenna made with coax pieces (omni
radiation pattern)
and a yagi antenna. Both antenna are matched to accept 50 ohm coax line.

I would like to know how to connect these two antenna on the same radio
using only
coax line.

The purpose is to give a max gain in one direction and have a good omni
pattern.

Is there a way to connect some coax to acheive that (I need a 50 ohm
line for my transceiver).

Thanks,

VA2 KWG

2397. Re: Newbie question: So why is my coax feed line radiating?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-03 03:24:47 UTC

Source record: 149382

your feedline radiates because the current in the antenna is not balanced (the same on each side).
when the current runs up the center wire, it flows out onto the leg of the antenna. when the current runs up the inside of the sheild, it can either run out on the leg of the antenna attached to the coax, or run down the outside of the coax. The various forms of chokes and baluns help prevent the current from flowing on the outside of the coax. There is no reason to put chokes at the transmitter end as there is no current flowing on the outside of the coax.
To help alleviate your problem use ferrite beads, add more turns to you bundle of loops, try a current balun, change the length of your transmission line, and make sure it runs perpendicular to the antenna. Also, make sure you have a short length of fat braid to ground your rig.
The problem with radiation from the feedline is that it can distort your radiation pattern, change the polarity, which may or may not be bad, but having the radiation in the shack from the rig and mike can burn you.
Other comment s, descriptions, and remedies welcome.

Source record: 149384

Coax choke or no coax choke, all feedlines pick up energy from the antenna
and re-radiate to some small extent. Nothing to be alarmed about.

What makes you think your feedline is radiating excessively? It probably
isn't.

If there's much RF in the shack it is probably due to the equipment and
feedline being in the near field of your 10m dipole which radiates a
powerful signal in all directions. A dipole is supposed to do just that.
Unless you live in a steel corrugated sheet house RF will come through the
walls of your house or shack without much difficulty.

You could try connecting the choke at the shack end of the feedline. A much
better choke on 10m is 4 or 5 turns of coax on a 1.5" or 2" diameter ferrite
ring. For lower freqs just wind on more turns.

2400. Re: Newbie question: So why is my coax feed line radiating?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-03 04:09:11 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C5CB7E7.170EBD0E@eznec.com>
Source record: 149386

This is a good description of one of the causes of current on the outside of the coax -- it's conducted from the inside, at the end of the coax where it's able to flow over the edge. The other cause is induced current from coupling with the antenna. Putting the feedline perpendicular to a symmetrical antenna minimizes this coupling, but it's not always possible to do. A current or choke balun will reduce the current on the outside of the coax regardless of the cause.

In the original posting, the question was asked if current got on the outside by coupling to the center conductor. The answer is no. The field from the current on the inner conductor induces a current on the inside of the outer conductor. This current remains inside the shield (except for a very small amount of leakage due to the shield being imperfect). All of the field from the current on the inner conductor couples to the inside of the shield and vice versa. This results in these two currents always being equal in magnitude and opposite in direction regardless of what you do to the outside of the coax.

Reg et al:

Common mode chokes/current baluns... Hey! Two common mode chokes can't hurt, in fact will often be much better than one big one, especially if spaced far apart.

Two chokes, each of a smaller inductance than one bigger one, one placed say near the bottom end of the coax, and the other at the top end of the coax will almost always be "better" than one choke placed right at the antenna feed point.

The common mode rejection of any choke or transformer is ultimately limited by self-capacitance.

Common mode choking impedance [inductive reactance] does not increase forever as you add turns/inductance to the common mode choke. The ultimate limiting factor for a choke is the parasitic inter-winding capacitance which allows the common mode signals to bypass or "blow-by" the choke.

To mitigate this effect the turns of the choke need to be spaced further from each other. The best way to do this is to create two, or even more, separate smaller chokes, each with less inductance, separated by a considerable distance from each other, this separation reduces the capacitance blow by of the common mode signals.

In fact, as we all know, this is why really effective rf-chokes are invariably constructed as "pies" connected in series with the pies separated from each other to reduce the inter-winding capacitance. The same is true for choke baluns, or so-called current baluns.

Pete, I know you know this -

If a feedline is coupled to the near field of an antenna it will re-radiate.
In fact *anything* coupled to the near field of an antenna will re-radiate.
It is impossible to eliminate the effect.

If you MUST have coaxial chokes, the best form consists of a ferrite slug
(a bead is a tiny thing you hang a string of round your neck) spaced every
1/8-wavelength along the coax length. Call it the G4FGQ distributed choke.
Lumping a number of ferrite slugs all together at one place is an
inefficient way of using them.

A single choke at one location merely shifts the current standing wave on
the outside of the coax to another location where it radiates just as much
as it did before. (That is, of course, if you believe radiation occurs
mostly from where the current is greatest such as at the middle of a
1/2-wave dipole antenna.) A choke fitted at an SWR current minimum has no
effect - it might just as well not be there.

The first thing to do when a choke is fitted and you have RF in the shack,
is to remove the choke. Removal of the choke is just as likely to get rid of
RF in the shack as when fitting a choke just because there might be some.

If you have severe RF in the shack (lips burned on microphone) the first
place to try a choke is where the feedline comes into the building or shack.
If you look out of the shack window and you have a broadside view of a 1KW
dipole there's nothing to be done except to try re-orientating it.

If your neighbors suffer from TVI one thing you can be sure of - it is not
getting into their house via your feedline !

Reg.

Is the ham actually gaining anything from it, or just trying to look
cooler than the guy next door?

Renting out space on a 150ft tower can be pretty profitable in the
right areas.

Source record: 149391

A while back I did some modeling of a ground plane antenna with a wire representing the outside shield of a coax feedline, with the feedline length adjusted to maximize induced current. With no balun, the current was maximum at the feedpoint, minimum a quarter wavelength below, and so forth. When I put a model balun (a fairly high impedance in series with the feedline wire) at the feedpoint, the induced current was just about the same magnitude. But it had shifted in position so the minimum was at the feedpoint, the first maximum a quarter wavelength below. All I had done was change the boundary conditions. What the model showed to be effective was placing a second balun a quarter wavelength below the first. That way, for the feedline nearest the antenna at least, the boundary conditions don't allow any of the possible full current distributions to exist, and the current is very low. Consequently, this spacing of baluns is what I recommend when more than one is used. I don't think that two baluns placed an integral number of half waves apart will be much more effective than a single one.

Very true - but it *is* possible to reduce the coupled currents below
the level where they cause trouble to either ourselves or our neighbors.
That's what we're aiming to do.

>If you MUST have coaxial chokes, the best form consists of a ferrite slug
>(a bead is a tiny thing you hang a string of round your neck) spaced every
>1/8-wavelength along the coax length. Call it the G4FGQ distributed choke.
>Lumping a number of ferrite slugs all together at one place is an
>inefficient way of using them.
>
That's debatable - it depends very much on the antenna/feedline setup
and the wavelength. There are two ways current can appear on the outer
surface of your feedline: electromagnetically coupled from the antenna;
and launched directly from the feedpoint connection, due to current
imbalance there.

The feedpoint is almost always the biggest source of surface current,
simply because there is a direct hard-wired connection to the coax
surface at that point. Therefore in most cases it's best to stop the
current being launched from the feedpoint first, by placing a
substantial reactance there. This can be done at almost zero cost by a
flat coil of coax which acts as a common-mode choke, aka current balun.
(A long string of ferrite beads will do the same, but it's very
expensive and heavy compared with a simple coil of coax.) To the extent
that you can prevent outer-surface currents at the feedpoint, you are
also forcing the currents in the antenna more towards symmetry. However,
it does need a substantial lump of inductance to do that - just two or
three ferrite beads at the feedpoint usually won't be enough.

>A single choke at one location merely shifts the current standing wave on
>the outside of the coax to another location where it radiates just as much

>effect - it might just as well not be there.
>
All very true (except for that slip of the fingers about "SWR current" -
go wash your hands with carbolic, Reg! :-)

When you force a current minimum on the coax outer surface by placing a choke there, the surface current caused by EM induction from the antenna will simply try to rearrange itself. With long feedlines and at high frequencies you will potentially have several maxima and minima, and trying to kill the currents completely is like trying to squeeze down a long balloon - wherever you squeeze hard, by inserting a choke that forces a current minimum, a new maximum will pop up a quarter-wavelength away.

Reg's distributed ferrite chokes will help keep the current down all along the line... but it's still best to kill the hard-wired current source at the feedpoint first. When you've stopped that one, it only leaves the EM-coupled component to deal with.

>The first thing to do when a choke is fitted and you have RF in the shack,
>is to remove the choke. Removal of the choke is just as likely to get rid of
>RF in the shack as when fitting a choke just because there might be some.
>
Removing a choke can never really cure the problem. Worse trouble is almost certain to reappear on a different band.

I would leave every existing choke in place, add more if you need them, but above all make sure that the choke right at the feedpoint is a good 'un. The ARRL Antenna Handbook contains details provided by W7EL for flat-coil chokes. The most effective ones are self-resonant on a single band, but there are also slightly less effective designs that cover several bands. You can also string together chokes designed for different bands.

>If your neighbors suffer from TVI one thing you can be sure of - it is not
>getting into their house via your feedline !

RF is slippery stuff, so that is not universally true. My neighbors share the same electricity feed, and once my RF was coupled onto my own electricity lines, it treated both our houses as one.

I wouldn't trust it self supporting, guys would be a really good idea.
If you're only putting up wire antennas, and don't care much if it falls
down in heavy wind, it might work self supporting, but not in my yard.

Dear people,

A few years ago I did sell all mine receivers and I want to start all over again as a SWL. Does anybody know what is a good receiver to start with again and what is on the market. I have a budget from 320 U$ (371 Euro). But I have another problem as well I’m moved to a new apartment and second floor in a flat and the roof is not flat but slanting (if I wrote it correct). I have a ceiling what I can use but there is still that antenna problem how can I solve this ?

Thanks for all the help in advance

Terry Mitchell

My Radio Shack field strength meter shows nothing in the middle of my
shack (which is 40 ft from the dipole as the crow flies) but reads
high near my mic and radio, and off the scale when put it near the
feed line where it comes in through my window.

BTW, I am using a deep-cycle battery to power the rig, so the RF is
not coming in through the house supply.

Hi AL,
what about a different flexible antenna?
Have a look to the ARDF site in the signature and click on (I'm sorry but it
is only in italian language) 'Strumenti'-> 'Antenne'->'Flextel23'.

2417. Re: Wanted 6 meter antenna advice

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-03 14:47:26 UTC
From: ac6v <ac6v@amsat.org>
Message-ID: <3C5D4D7E.2D22DE88@amsat.org>
Source record: 149406

Hi Chris maybe make your own, using 234/freq, a six meter vertical dipole would be 4.67 x 2 = 9.34 feet. Feed it at the center and run the coax at 90 degrees to the dipole. Check and trim for best SWR.

A ham here (San Diego) running 10 Watts has woked 24 states, mostly New England but also Alaska, Hawaii, Puerto Rico and Cuba with this antenna.

Your mileage may vary

hey chris
i would suggest either the M2 HO loop or the PAR loop they would give you horizontal polaration which would be fine for SSB

Hi All,

Looking for personal experiences / info to help me decide which mini beam to buy.

I'd like to operate 10/12/15/17/20m from a single mini beam.

Look forward to getting some replies.

Mike,

I have a Traffie Technology HX5Bi due for delivery this week. It gives actual gain on all those freqs. Everyone I know with one is very satisfied. Check their web page:
http://www.hexbeam.com

One cavat.... it's not cheap. The price went up about $300 the first of the year. But..... a TV rotor will turn it and you can mount it on a push-up pole if needed. It weighs only 20 lbs and due to it's design it has very little wind loading..... 3 lbs or so.

Mike

Hi Michael,

The antenna looks most interesting, however it also looks extremely large on
the photos detailed on the website !

I was hoping for something a little more compact ??

I've got a very small plot to try and squeeze an antenna into :)

Any other suggestions ?

Thanks !

From: fractenna@aol.com
Message-ID: <20020203110356.12872.00000853@mb-mk.aol.com>
Source record: 149411

May I suggest that you dig out Don Meador's book on 'Analog S.P. with LaPlace Transforms and Active Filter Design'? Although somewhat pricey (albeit typical for today's editions) it is quite useful for beginners.

To answer your question succinctly: if you can look at the transfer function over its entire domain, you can get a good handle on its type. But most people don't approach it that way. Instead they try to find the filter type whose ripple is tolerable for the given application. In other words they start with the filter type and then look at the transfer function--relative to the practical need.

BTW I prefer to work in poles and zeroes. Makes me an old timer:-)?

Kindly let me suggest that you not try to hit the job market with knowledge you are in the process of acquiring, but try to emphasize your best extant skills.

Best wishes in your efforts.

Hi Roy,

Here's something I discovered for modeling a bead type balun For
2-meters. Such a balun is around 8" long. Therefore I modeled wire
representing the outside shield using 2" long segments. Then I placed
four 250-Ohm inductive loads - one on each of the first four segments
at the antenna end. This produces a model which, I feel, more closely
represents the actually installation. The results were notably better
than using a single load on one segment.

no the purpose is only to accentuate a little in one direction, keeping the
omni pattern

resuming that , I only want to connect 2 antenna on the same radio, transmit
and receive on both antenna at the same time

Thanks

[snip]

No! Poles and zeros doesn't make you an "old timer"! Just a pup, heh,
heh...
If you were an old-timer you would use "image parameter design" methods
and the cookbook tables from the old ARRL handbooks and other such.

Hi Phil

It is a bit unclear, but there are actually rear-view mirrors that facilitate turns.

Look carefully at the top (exterior) photo and you can see them. In the bottom photo look behind the steering wheel and inside rear-view mirror and you can see the (out-of-focus) exterior mirror.

Wes

Yes, that's not right.

Put some more 'thot' into it and you may come to the realization that
bachelors are masters of their own households far more often than
non-bachelors.

> What then? How does one qualify to get married and have a family?

There are usually no qualifications; one merely finds an agreeable
(hopefully) companion and then buys a license.

> What schools do ya have to attend?

None

> Where do ya find the wimmin? etc...

They're everywhere. Look for the people with tits.

> HAM RADIO IN SPACE: HF ANTENNA INSTALLED ON ISS
>
> High Frequency ham radio operations from the International Space Station
could
> be on the not to distant horizon. This, after a successful space walk on
> January 25th to install another antenna on the orbiting outpost. Amateur
Radio
> Newsline's Roy Neal, K-6-D-U-E, has the details.
>
> --
>
> The spacewalkers have had another good day in space. On Friday the 25th
of
> January, Cosmonaut Yuri Onufrienko, RK3DUO and Astronaut Dan Bursch,
KD5PNU,
> successfully mounted a second ham radio antenna near a docking port
amidships
> on the International Space Station. It is made of flexible tape and is
similar
> to but longer than another antenna installed on January 14th. That one
tunes
> both VHF and UHF frequencies. The new antenna will tune HF frequencies.
>
> ARISS Board Chairman Fran Bauer, KA3HDO, says it definitely will work on
ten

> meters and may even be made to work on 15 and 20 meters. BUT right now
there
> is no gear on board to handle those frequencies. Experiments using the
lower
> frequencies are on the list of futures for ARISS but no timetable has
been
> assigned to design and build them.
>
> Owen Garriott, W5LFL, the first man to operate ham equipment in space,
once
> prophesied that a five watt transmitter in orbit might well be heard
> simultaneously world wide. The great number of hams with good stations on
the
> lower frequencies also makes them enticing to ARISS. It's a safe bet that
> serious consideration now is being given to expedite such a project. Once
a

Well, that was welcoming to a newbie...

>There are many books

Only one book that I know of - the ARRL Antenna Handbook - talks about the practical problems of RF on feedlines and how to cure it.

He might be lucky enough to find something in a back-issue of some magazine... but as a newbie he probably won't have those.

> and courses

Really? Please name even one that deals with this subject, in the practical terms that he needs right now.

>and clubs.

Where he may find equal parts of fact and folklore... and for a newbie, it's hard to tell the difference.

I think he's come to the right place. All the answers offered may not agree, but he'll learn plenty from the discussion.

Hello,
Kind of a long post. I'm in the process of setting up a a brandy new station/shack. Good news I have a whole room to myself.(Kids moved out.) Semi good news, it's on the second floor. My question has to do with grounding both for RF and lightening. In what I've read, most sources call for a ground run to be as short as possible. In my case about 20 feet. Also, some sources say multiple ground rods, about 8 feet apart bonded together.Does this add into the length of a ground run? As for bonding, some sources say that all your grounds (Cable TV, Telephone, electrical service, etc.) should be bonded together. Other sources say that the shack ground should be isolated (Don't use the electrical outlet ground, or a nearby cold water piper for example.) I've read that your equipment ground connections can be all terminated on a grounded copper buss bar. Others say never daisy-chain your equipment. Very confusing for a newbie. Any advice, steering in the right direction, etc. would be greatly appreciated.
Thanks,
Ed S

2437. Newbe - Build an antenna switch

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-03 19:13:12 UTC
From: Scott <GAEL79@Peoplepc.com>
Message-ID: <u5r2ujfg9v1q3f@corp.supernews.com>
Source record: 149275

Hello All, I would like to try to build an antenna switch for HF. I know I can get the connectors at Radio Shack. I am pretty handy with sheet metal (aluminum), so I don't think the case will be a problem. I am just starting in the hobby, but would like to build it to run legal limit. Does anyone have any experience doing this? any advice on the switch or wiring technique inside of the box, would be appreciated. Is it best to use short sections of 50 ohm coax between the socket and switch and ground the box separately, or just use solid copper wire for the positives (center conductor), and use the box as the ground? I assume either way I should ground the box to my "station's" grounding buss. Is this correct?

Thanks for the help.

Scott

Date: 2002-02-03 19:23:49 UTC
From: Scott <GAEL79@Peoplepc.com>
Message-ID: <u5r3id27t1i1f4@corp.supernews.com>
Source record: 149277

Hi,
I am just starting to set up my first HF station (10 - 80 meter). I just set up an 80 meter, 1 wavelength horizontal loop antenna. So far, all of my HF gear is Heathkit, around the same vintage. I am now looking for a tuner for the loop antenna. I was originally going to stay Heathkit, and go with the SA 2040, but I have read some O.K. reviews of the Murch UT 2000A, and it looks like they run a little cheaper on the used market. Can anyone help me to "Get off the fence" and pick a tuner?

Any comments from users of one or the other or both of these will help me to decide.

Thank you for your input.

Scott

2440. Affect of limbs and leaves on wire antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-03 19:35:14 UTC
From: Mike Jordan <mjordan@europa.com>
Message-ID: <3C5D90F2.9030803@europa.com>
Source record: 149278

Sometime before the leaves start coming out on a big Elm tree that is in our front yard, I want to try and get the end of a 80 meter dipole I have going to it up higher than it is now. Currently I have the guy rope about 25 to 30 feet over a limb. The end of the rope connects to the end insulator of the dipole about 15 feet out beyond the limbs and leaves. I want to take the rope up another 10 to 15 feet higher, but the best limb for that is actually on the other side of the tree. Since I would like to shift my dipole that way anyway (I have it in a 90 degree angle now with one leg going North/South and one leg going East/West) so as to give me less of an angle at the center. I know that when dry, I shouldn't have too much of a problem with the leaves and finger size limbs that will grow around it, but how about when they are wet? Can I expect this to affect the tuning of the antenna by very much? Approximately 15 to 20 feet of the one end will be within the tree growth area. The antenna is made of non insulated copper wire. I am thinking of changing this antenna for one of the Alpha Delta 80-10 dipoles when I do the work. I only use up to 100 watts from my Icom 745 with the AT-150 antenna tuner.

Thanks.

Running just 9.5 watts here with a 3 el beam (up at 7,745'), I've
worked 49 states. Still chasing the elusive R.I.

Best DX: VK8MS.

Worked Tim, V73AT yesterday afternoon - 3 other new countries in the A.M.

I've worked other fellas that were running far less power, or far
less 'desirable' antennas than I -- usually Great Sigs, nonetheless.

Six Meters is a Kick In The Pants!

I have the AEA-CIA which is very similar to the VIA, but less money. I used to have the MFJ-259B but gave up on it after it broke twice. The MFJ is actually a nice unit except for the poor build quality. Several other people I know have also had theirs fail. Battery life in the MFJ is very short. I was constantly annoyed when the unit would stop working in the field because the batteries had run low.

The AEA has much better build quality, although it costs quite a bit more than the MFJ. It's advantages are the graphical display and the ability to download data to a PC. AEA also has a data acquisition and plotting program which allows you to generate automated frequency sweep plots on your PC. It's very handy. Battery life is much better than the MFJ. As for price, I ended up buying direct from AEA Wireless at list price because I couldn't find any dealers (are there any?).

I don't have any experience with the Autek.

Dick,

Using the label/visual method, you shouldn't have any trouble with mistaken resonance. Since
you are already near the correct resonance by sighting the antenna, you shouldn't be crossing
the 3/4WL point anyway.

On the point of 'wasting' a 259 for tuning the antenna, I don't consider it wasted since it is
removable for other uses. Heck, if it weren't being used for this purpose, it would just be
sitting on the shelf until I needed it. It is also very precise since I can also observe for the
closest impedance match. I once suggested to MFJ that they design a screwdriver auto-
positioner based on the 259 since most of the compoments were already there. Seems AmCom has beat them to it. That is what I want next.

Ian, when a balanced 1/2-wave dipole is fed with coax, what fraction of system input power is radiated from the feedline ?

Compare that with what is radiated from the dipole and ask yourself what is the likelihood of the unbalanced feedline being the source of any TVI which somewhat rarely might exist in the neighbourhood.

Yes, except that my Am Com controller sometimes has a mind of its own
and starts off in the wrong direction. I don't think it is the Am
Com's fault. I have a problem in the antenna that I haven't had time
to resolve yet. When I try to find the resonance point with the
MFJ-259 it won't sit still. Could be water in the toroid or an
intermittent in the fiberglass whip. Maybe RF on the coax or control
cable. OK, I admit it. It's too darn cold outside to work on the
antenna.

I have a design that takes one ten cent IC and one $3 relay. The
operator chooses the direction. If the reflected power pickup
voltage is more than a certain voltage (selectable from the front
panel) the antenna moves until the reflected power pickup voltage
is less than that certain voltage. I use the reflected power pickup
voltage from my Daiwa SWR meter and the extra IC, relay, and direction
switch are built into the Daiwa enclosure. It's as slick as owl poop.

Hello All;

I live an a development in California that has CC&R's, restrictive to all types of external antennas, including satellite dishes. I need to erect an antenna to use with my amateur radio, and I was wondering if anyone else went up against CC&R's with an antenna, and what was the ending result. CC&R's are part of every new development out here; you can't buy a new house without them, effectively eliminating amateurs from operating. My CC&R's are not even linked to a homeowners association, so I am wondering how enforceable they are.

Any comments or suggestions are appreciated.

hey dont let them BS you there are many ways to play radio with out them even
seeing an antenna check your restrictions and if you can have a flagpole you can
make one out of PVC pipe and hide a multiband HF vertical inside of it
or you can string a wire around the roof line of the house telling the housiung
nazis that it is an antifungal strip what do they know...grin just buy a bunch
of those 1 inch stand offs from radio shack and string the wire thru them and
then run it into the house to a tuner
there are also ways to play VHF/UHF there is a weathervane antenna as well as
the ventenna so you can play it just takes a little effort and thought
or move...grin
good luck

Verticals don't seem to work (crappy soil conditions, and I don't have room for radiators. All houses in the area are two story houses, so I really want to get the antenna above them also. I also have a nice beam that I want to put up. I just want to try to buck the system, and wanted advice on it. If it doesn't work though, I certainly will try the stealth approach.

If you own the property, CCR's can't stop you from putting up a satellite dish less than one meter in diameter. They can stop other types of antennas. They are enforceable by those who wish to pursue it through the courts. About your only recourse is to use one of the various kinds of stealth antennas. I would try the attic if you have one.

A CC&R is a legal contract that you signed and agreed to. It is enforceable just like any other contract - especially in the People's Republic of California. But, like any other contract, if you have enough time and money you might be able to obtain some type of compromise or variance.

(Actually, there are a lot of houses in CA without any antenna restrictions - depending on where you want to live. When I bought my last house I saved myself a lot of grief by telling the Realtor that I was only interested in looking at houses that did not have any anti-antenna CC&R's or local ordinances. And before I signed the purchase agreement, I had this fact stipulated in the disclosure documents)

However, if you have an attic that you can string a dipole up in, you can still get on the air. It won't perform like a yagi at 80 feet, but you can still work the world with 100 watts...

Good Luck,

73 de W6DKN

[snip]

Your point is well taken for the transmit direction.

However for the receive direction when trying to pull weak DX signals out of
the mud with high sensitivity receivers, the
common mode noise pickup, the ITV, can often be extremely troublesome,
especially if the "unbalanced" feedline passes
close to television sets.

I have found that good common mode rejection principles applied to antenna
feedlines
helps more with reception problems than with transmit problems. Especially
with weak signal work.

Dick Hughes wrote:
> Well, are you going to share it Cecil?

The IC is an LM339 quad comparitor. All four stages are paralleled. The '+' inputs are tied to the centertap on a 10k pot. The other two terminals on the 10k pot are tied to +12 and ground. The pot furnishes an adjustable reference voltage. The '-' inputs on the LM339 are tied to the reflected voltage output from the shielded can in the Daiwa SWR meter. The outputs of the LM339 drive a SPST 12v relay. The relay contacts furnish the +12v power to the familiar DPDT direction switch which is not a momentary switch anymore.

If there is no reflected power (receive) the relay is off and no power is applied to the screwdriver motor. When reflected power appears and the pickup voltage is above the threshold, the relay picks up, furnishing power to the DPDT direction switch which must be set by the operator. When the pickup voltage from the reflected voltage output falls below the level preset by the pot, the relay falls out removing voltage from the screwdriver motor.

<G3SEK@ifwtech.com> wrote:

>Only one book that I know of - the ARRL Antenna Handbook - talks about
>the practical problems of RF on feedlines and how to cure it.

I secured a copy of the the ARRL Antenna Handbook and have read the section on this problem. It covers the subject in greater detail than the ARRL Handbook, but it is still not rigorous. It explains -- as was done here -- why coax is "unbalanced": Current travels the inside of the sheath but at the antenna feedpoint some of that current fails to flow out onto the dipole leg but rather flows down the outside of the sheath, whereas all of the center conductor current flows into its dipole leg. It still sounds kind of circular, because it does not explain why the current finds the outside of the sheathing a suitable path to follow. Also, the concept that the inside of a thin good conductor is at one potential while the outside is at another is counterintuitive.

Anyway, my main question did not really get answered, although other questions did and the information was helpful: I already had installed the recommended coax choke and was wondering why I was still getting RF off the coax, insmuch as the coax choke was supposed to be very effective with a monoband dipole.

The Antenna Handbook had a little more detail about these chokes, distinguising between flat-wound and scramble-wound. Mine is scramble wound. Tomorrow I will wind it flat around a section of 4" PVC sewer pipe and see if that helps. After that, I will try a Hi-Q 1:1 current balun. After that, the ferrite beads on the coax.

Hardly worth building one.. they're dirt cheap on E-Bay or Radio swap. But if you feel the need, use solid wire inside, and keep it as short as you can. For legal limit, you'll need a really good switch which might not be easy to find.

Thread:

An interesting story...

Although the percentage of women in Engineering is not very high, for some reason unknown to me, I personally have
enjoyed the opportunity to work with several very fine female Engineers.

During one three year period in my career, I had reporting to me among my staff three excellent women Engineers. All three became
pregnant, by their respective husbands, during one 12 month period! Barbara, Caroline and Iris.

I recall working with one of our lovely Engineer mothers-to-be late one Friday night, on a multi-million dollar project, in which she
had played a vital design role, and for which customer acceptance tests were to be the following Monday. I wondered that Friday
afternoon why Barbara wanted to work late on Friday instead of coming in on Saturday and Sunday. She must have had a
premonition...

In any case, we got all of the final bugs out of the acceptance test procedure, never could have done it without her, around 9:30pm,
and some of the male Engineers wanted to go have a beer, it was then she told me that... I should call her husband and drive her
to the hospital! This was somewhere around 10:00pm that Friday night. Wow! She had been in labor for several hours that
evening and just kept working with us in the lab till we were done, because we needed her, and she never said a thing!

With her help "we" delivered both the project and the baby in good health!

Later, my wife Mary wanted to know why I sent Barbara a bigger bouquet of roses than I ever sent her when she was delivering our
own kids... heh, heh... My dear wife still doesn't understand Engineers and their projects!

To this day, that little girl, Barbara's daughter, is one of my sweethearts.

I have the Heath SA-2040 and I like it fine. I can't compare it to the
Murch--I just know that
I had a 2040 once and foolishly sold it at a hamfest. It didn't take long
to realize that I had
made a mistake! So, I found another one, and I'm keepin' it! The Heath may
be higher, but
I don't think it is "overpriced"; it, after all, does what it was designed
to do. And I HATE tuners! Hope that helps.

Dick,

If *I* were having that problem, I would suspect the toroid first. I don't even use them in my
screwdrivers. I use either a small coil of about 6-8 turns paralleled to ground (Trim or add turns as needed, or I use another inductor (2") in series and tapped to ground off whatever
turn gives me the 50 ohms. I found toroids to be "finicky" and prone to trouble--especially on
10 meters. They would act "funny" as you describe and refuse to tune, or tune one way one time, another way another time. Next, I would wind a coax "choke" about 6 turns on an 1 1/2"
dowel or similar form and tape it to hold its shape. You can remove or leave the dowel. That
usually gets rid of RF on the shield. It is also pretty effective if you have odd things happening
on various frequencies; lights a-flickerin', windshield wipers a-wipin', and washers a-washin' when you don't want it. My other car's wipers and washers would fire off before I did the
choke thing. ...just a couple of ideas. OH, the choke goes right at the antenna.

Thanks for the ideas. (And thank you too Cecil.) I went through some
really bad weather last month, and drove into the garage with the whip
still on before that (Ouch, ouch.) That's why I think either the
toroid is swimming inside the box, or I broke something in the whip.
Could have damaged the coil fingers as well. I just have to get out
there and check everything out. It did work fine before all that.

Dick

Nice Discussion. Regarding Ferrite Beads, there are several cheap places (Marlin Jones for one), that sell these clamp on (they're split in half) ferrite chokes used primarily for CRT monitor video cables. There is one with a half inch ID. You think these would work well? Certainly cheaper than the real McCoy.

They know that if it really is an antenna, you could be in big trouble.

Read the CC&R's very carefully, including the part about you paying
attorney's fees and penalties.

Best to use an indoor antenna. Properly done, they work quite well.

That's very interesting. In my whole career, I worked with only one female hardware design engineer. She was an ME and unfortunely not much good (which in no way do I attribute to her sex). There were quite a number of female software engineers where I worked. I didn't work closely with any of them, but as far as I know they were competent.

One thing I do know for sure is that computer antenna analysis is a guy thing. Fewer than one in a thousand EZNEC customers are female. (There's always the chance, though, of something like I saw in a grade B movie not long ago -- the main female character went by "Jimmy". When someone finally asked what it was short for, she replied, "James. My parents really wanted a boy.")

I was just looking at one of those. Can't believe they now punch a hole
in the roof (in a really dumb position) to permanently mount an On-Star
antenna.

Do you have the roof rack? How about a bracket off that?

Steve

For some phenomenal noise reduction on all bands / all modes try the ClearSpeech DSP Base Unit Noise Filter. Ever since installing mine a few months ago on my TS450S/AT it has been like having a brand new radio...or maybe better said it is like having new Ham bands to enjoy. The outstanding effectiveness of this product stems from the licensed and proprietary algorithm that is used. No one else has it including the HF rig manufacturers themselves.

My friend AC6AA uses one with his FT-1000MP and leaves his built-in DSP in the Yaesu turned "off" because the ClearSpeech unit is so much more effective. There several reviews of this base unit and also the available mobile speaker version at this URL....

http://www.eham.net/reviews/products/6

I am posting this as a possible alternative method to solve noise problems....photos and description and technical data on the ClearSpeech DSP base unit on my web site listed below...

Ken wrote:
"It still sounds kind of circular, because it does not explain why the current finds the outside of the sheathing a suitable path to follow."

There is a difference of potential between the inside and the outside of the coax sheathing at the point where the dipole is fed, so current flows between the connected points of differing potential.

Suppose the outside of the sheathing is well grounded at the radio, and it measures 1/2-wave at the signal frequency. At the dipole feedpoint the potential will be almost the same as the ground potential. The potential inside the coax sheathing will be different because the velocity of propagation is about 2/3 of the velocity on the outside of the coax. There will be a phase difference between inside and outside of the coax and thus a voltage difference.

The 1/2-wave of coax repeats the earth impedance and thus offers a low-impedance to the signal at the dipole feedpoint. Why wouldn`t current flow onto the outside of the sheathing?

Ken also wrote:
"Also, the concept that the inside of a thin good conductor is at one potential while the outside is another is counterintuitive."

Not when "skin-effect" is understood. R-F does not penetrate a thin good conductor if that conductor is not too thin. It doesn`t take much thickness with a good conductor to bar r-f current from flowing through the thickness of the conductor. The thickness of the coax sheathing was chosen to prevent penetration to prevent ingress or egress of signals directly through the coax sheathing. It works. Coax, as a result, doesn`t care much how it is routed.

Best regards, Richard Harrison, KB5WZI

Check the ARRL site first. They have a lot of current information and
even have a book on the subject. There is also a federal law that says
they have to "make reasonable accommodations" for your antennas. It may
take a court fight to make them comply.

Look around the neighborhood for other antennas. 8 Ft dishes in front
yards or 100 ft CB towers may mean they are not enforcing the CC&Rs.
Read your CC&Rs! This month's QST has an article about a ham that won!

I have a 1026 and I use it often. My neighbor has a 50" TV that has a noisy switching power supply that registers about S-5 on 17 meters. I used wire on my fence to make a "noise antenna" and feed it into the 1026, I have another run below my TV to do the same (not near as bad). If only one of the TV's are running I can phase the interference completely out, if two down to about 1 S unit. By the way get the 1026 not the 1025 (if you go MFJ) because the 1026 has a preamp that helps greatly (or add one to the 1025).

If there is a roof rack, mount an antenna there and route the wire
through the seal on the back door. You can also mount a through the
glass antenna on the front, side or rear glass if you stay clear if the
defrost wires.

I found a hole already in the roof of my 99 Yukon covered with a rubber
grommet. I routed a wire through the air duct covering down the side
pillar to the floor. pretty easy!

Hope this helps,
Les, AA4F

Thanks guys. It seems to me that the CC&R's have been "abandoned" in my area (at least that is what my argument will be), based on the fact that they are not enforcing the ban on satellite dishes, cars parked in the streets, basketball hoops left in the street, odd window decorations, etc. They can't be selective about only enforcing my violation.

You may have a good argument here. However, forget the satellite dishes unless they are the big ones (BUD.) If you live in a private residence, the Telecommunications Act of 1996 pre-empts CC&R's concerning small satellite dishes and TV antennas. Focus your argument on the other issues.

Scott,
It's more a matter of personal 'taste' than performance.
Both tuners work okay, so do you want matching styling or to
save a buck or two?

I don't know, because I have never seen a truly balanced dipole fed with coax. It only exists in people's imagination, like the Emperor's New Clothes.

The general case is that there *will* be surface currents. They only go through a minimum in one very, very special case, but they never go completely to zero.

>Compare that with what is radiated from the dipole and ask yourself what is
>the likelihood of the unbalanced feedline being the source of any TVI which
>somewhat rarely might exist in the neighbourhood.

I do know that surface currents can cause RFI - either in the shack, in the house or to neighbors. Unlike the radiated component, they have the advantage of a hard-wired connection.

This does not apply to CC&Rs - only to local/state laws and regulations.

> Look around the neighborhood for other antennas. 8 Ft dishes in front
> yards or 100 ft CB towers may mean they are not enforcing the CC&Rs.
> Read your CC&Rs! This month's QST has an article about a ham that won!

It would be nice if the courts were consistant in such rulings. But
this is the first, if it is indeed about beating some CC&R.

That is exactly true. Either they all have to be enforced - or none can
be enforced. Of course, you might have to spend a bunch of money in court
to get relief.

2511. Help wanted - Quagi Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-04 11:41:15 UTC
From: Radio Jav <antispamradiojav@bigfoot.com>
Message-ID: <Dnu78.13914$N31.646027@ozemail.com.au>
Source record: 149348

Hello from the land down under (Australia).

I have a question for you antenna gurus out there, my question pertains to the design of Quagi antennas. I am looking to design a Quagi for use on 477Mhz, a community, citizens band frequency, not to dissimilar from HF CB Radio.

How does one go about designing a Quagi antenna? Does one use a JavaScript quad calculator for REF and D/E measurements and spacings, then use a Yagi modelling program, such as YAGIMAX to design a Yagi for the given frequency, then use the quad REF and D/E on the Yagi? (did I say all that in one breath? Hi hi...)

I am not a technical wizard when it comes to mathematics, but love to experiment with antennas and the like.

Many people operate on 477Mhz with Yagis with very good to excellent results. I have read all about the Quagi antenna and would love to tinker with one on my current frequency of choice.

I am currently studying for my Amateur licence and feel that building this antenna would put a lot of theory into practice. I am looking at building a 10 element and 16 element version of this marvellous antenna.

My last question pertains to co-phasing a pair of these antennas. Does anyone have a phasing harness diagram that can assist. I have found a Phasing harness diagram for 4 co-phased, but not two.

Thanks for your time, many warmest regards to you all.

Please either post to the NG or direct to my email address, just remove antispam first.

Thank you in advance

Source record: 149349

I live within 100 meters of three (3) sets of electrical New England Power Grid power lines [> 100,000 KV]. Sometimes they get very noisy.

The ANC-4 will reduce the noise by up to 8 S units. Works great on MAN-MADE noise.

The ANC-4 class of noise reduction is much more effective than any DSP based reduction because the noise doesn't get into the rf or if amplifiers or AGC system. No noise inside the radio, therefore, no need for DSP noise reduction.

Atmospheric absorption/noise on 80/75 meters during the daytime is not man made noise!!

Reg,

>Do women make as good engineers as men ?

Yes they do.

There used to be a west coast US broadcast engineer by the name of Amor powers (no pun) who frequented several newsgroups.

She won several engineering awards in the industry. It was nothing for her to design and help install 50Kw stations from scratch.

Amor had an ex school bus with a 40m DDIR on the roof and 'a very powerful' amplifier on-board.

You'll also find many female experienced engineers in the former soviet union!

But why use a screwdriver on a stationary (from another post) RV?
They're FB for mobile in a car or truck but there are perforce
compromises to get that mobility; compromises which may be unnecessary
in your application. For example, on Field Day we used a homebrew 1/4
wave vertical for 20M and put a pully on top so we could pull up an
inverted V cut for 40m that also worked 15m ... all made out of free
junk ... plus a tuner we'd bought for $40 at a hamfest. Another RVing
Ham does the same using a collapsable flag pole he got from Camping
World.
Longer is better!

Sure (wink), CBrs "cophase" their antennae all the time. It can be done
within a narrow freq band by using specially cut lengths of coax. Sorry,
I don't remember the formula but somebody here otta know how to
calculate the lengths. You might have to use 75 ohm coax.

Ian, what may be picked up and re-radiated due to an assymetrical feedline
is the same whatever form of construction the feedline might be and can be
left out of the comparison.

Here we are concerned only with the fraction of Tx output power radiated
from the feedline due to the 1/2-wave dipole being fed with unbalanced coax
rather than balanced-twin.

There are two conductors in a balanced feedline. With coax, there is
effectively a third conductor. If you hung a separate conductor down
from one side of a dipole fed with balanced line, don't you think it
would radiate? Especially if it were a resonant length?

Reg:

Heh, heh... That fraction is indeed small and would be determined by the Common Mode Rejection Ratio of the antenna "system".

In most any kind of system, let alone an amateur antenna installation, the measurement of CMRR is problematic, and usually beyond the kinds of metrology that a typical amateur can muster. Measuring the CMRR of a simple transformer or differential amplifier is difficult enough.

That said, from long experience measuring CMRR in various situations at various frequencies using professional equipment and methods, I'd hazzard a guess that for a typical amateur installation, the CMRR for a given low frequency band might be on the order of 15-20dB at least. Could be more could be less. Probably less on the upper HF frequencies, the higher you go in frequency the more difficult commom mode control becomes.

Say the CMRR of the antenna "system" is CMRR = 15dB, then the "fraction" of which you speak is 1/(10**3/2) = 1/31.6 -or- around 3%.

The amateur using a 100 Watt transmitter to push 100 Watts into that antenna system with a 15dB CMRR will be pushing about 97 Watts into the differential modes and 3 Watts into the common modes.

Reg, depending upon the impedance levels of course, 3 Watts has a non-negligible effect when placed at the terminals of a sensitive receiver or across a pair of moist lips touching a metallic microphone grill, or a bare hand touching a Morse key.

Best,

You must not be too familiar with RVing!

Sure, SOMETIMES an RVer IS fortunate enough to be in a site where larger antennas can be used - but
usually NOT! We aren't talking about field day type operation here, but ham operation in situations
where your RVing neighbors (NON-ham!) are all within a few feet all around you! The LAST thing you
want is any more intrusion into the "ambiance" of the setting than necessay - NOR do you want a
steady stream of RF-related complaints as your ham setup is clearly visible from MANY areas of the
campground. Even an ordinary screwdriver is too much of a stretch in many such scenarios! SOOooo,
sometimes (ususlly...) you are forced to use the best available compromise in order to use your ham
stuff.

> Roy Lewallen, W7EL

Hi Roy,

thanks for your suggestion.
As I said in another post, I'm using a three element yagi 'flexible', but
without any balun.
Since the radiating element is a folded dipole, I only matched its impedance
(about 100 + j 10 Ohms) with a quarter w/l of 75 Ohms TV cable.
Do you think I really need a balun? If yes(as I think) can you send me a
schematic for a balun 2:1? I have the wonderfull book by W2FMI, but I
couldn't find anything for VHF.
Thanks in advance.

Well, from my experience in amateur radio over the many years, I have found that most negroids cannot learn anything that requires math. I know that sounds very biggoted but our Zionist government is pushing them to be among the white middle class people and breed with our kind. As far as Colon Powell goes, he is just a token black to appease the black population. He didn't even finish high school I understand.

If you want vintage, and want a Highly efficient inherently balanced antenna tuner, Look for a Johnson Matchbox. The pretty ones are $100 on Ebay and the "previously modified" ones are around $50. I used mine on a 210 foot horzontal loop on all bands (including warc). I used 300 ohm ribbon line for the feed.

You're right. I've only owned my MH for 3 years. We did full-time for 3+ years but that was circa 1980 and in the USA vs PRK.

I question the sanity of semi(?) permanently parking where there were neighbors "within a few feet all around you!", a-la the Flying-J, let alone worrying about the ambience of such a setting; but then I don't live in an apartment either.

> ....NOR do you want a

>

1) the screwdrivers I've seen are as obtrusive as many alternatives, including my buddy's "flagpole" or the 16.75' piece of tapered alumunum I put on my ladder for field day. 2) when full timing I had 30' of TV mast holding up my V/UHF and an inverted V cut for 40m. In 3 years nobody even commented on it, let alone complained (They thot the V was guying the mast). Last but not least, a Toyota minivan isnt considered a MH outside Ca. I have a plain whip and automatic tuner for actual travel and for over-nighting in truck/rest stops but it is a major compromise. That's why I'm looking at running some wire just off the 8x32' rubber roof. There's enough room for an invisible 20m Horizontal dipole up there! :o) Try it, you'll like it.

Though Cushcraft has had a number of customer support complaints,
this particular antenna (MA5B) is very well liked:

http://www.eham.net/reviews/detail/340 (eham.net product reviews)

If I was looking for one, that might very well be the choice.

No, it's a hobby, and CW is no longer needed to enjoy it. We are allowed
to do things that could QRM others -things others are not allowed to do
- so it is reasonable for governments to require us to have know how to
avoid that. It *was* reasonable for governments to require CW when that
was the only way to communicate; but that day is long past.

There is nothing wrong with *enjoying* CW for it's own sake but it is a
serious character flaw to feel that everybody should suffer every
discomfort that we did.

If that's going to be your argument, and not being a lawyer I don't know how legal it'll be, make sure to DOCUMENT all of that BEFORE you take any other action. Take lots and lots of photos, preferably ones with the date showing in the corner if you have one of those type cameras.

Also, you might look into efforts to get PRB-1 rulings enacted as state law in your area. Your ARRL section leaders might have more info on this.

I just finished installing my 10GZ DB6NT transverter with 2 watt
amplifier on my tower using a weather proof box and 144 mhz for the
IF.
I know this may seem a dumb question but what frequency is used at
10368 MHZ. Is it 10368.1 or 10368.2 for narrowband CW and SSB? Thanks
AL K3ROJ

The original question was about coax, and why a single choke coil didn't seem to solve the problem. By all means start another thread on this new topic of yours, but let's not complicate this one.

The Cushcraft MA5 is much, much better than the Butternut. See my prior posting.
Good construction, solid engineering, quality parts. Performance is very good null off the side is 3-4 S units with the antenna not yet at full height (Only 12 feet above flat roof at 18 feet. I expect it will be much better at it's full height of 30 feet above the roof.

2539. Stealth antenna feedline?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-04 19:17:00 UTC
From: Marty <nfn04028@naples.net>
Message-ID: <M6B78.9297$3E5.742016@newsread2.prod.itd.earthlink.net>
Source record: 149176

I now live in a place where outside antennas can't be used. The usual flagpole, birdbath, attic, and all those exotic alternatives are not feasible. And inside antennas are practically useless because the building is constructed with concrete, rebar and steel studs.

The only place that might be used is inside of a porch, adjacent to a screen (non-metallic). The screen frame (aluminum) measures 21ft across and 10ft high. I would like to put up something usable on 20M and am considering a drooping dipole, the ends hanging down about 7ft. I've used this configuration before at a different location but with ladder line and a balun which made it easy to match.

Now I'd like to use a feedline that is much less visible. I'd appreciate any suggestions and general comments on the whole idea.

If I had my druthers, I'd try to split the screen frame at
the bottom, and
use epoxy to fill in the gap. Then I'd feed that gap with
open wire line and use the frame as a loop (fed through a
tuner). This assumes that the scteen frame itself is
isolated from anything metallic.

Ooh. Hadn't thought of the other grounded metals with earth-contact.

My electrical service is grounded thru a single driven copper-clad
rod. The house and well are all done with galvanized steel pipe. I
wonder if my 25 year old plumbing or ground rod is corroding away...
Running new pipe from well to house will be _extremely_ unpleasant.

I was just about to bond three or four more copper-clad rods to the
existing ground rod (2/3 driven, wire run 3/4 of the way around the
house, 3rd rod waiting to be driven, 4th is a maybe).

I suppose before I bond to the existing rod I can check for galvanic
potential between new electrodes and old ground system. A big
current flow might accelerate deterioration of the well casing+pipe.

> Although in many installations, earth electrodes last a very long time,
> one should expect to make periodic inspections and measurements to
> ensure that they continue to be fully effective.

Decent, meaningful ground measurement is a pain.

2543. mono multifreq antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-04 19:56:29 UTC

Hi,
I see there is another three element antenna on the market
on a 18 foot boom.(Fluidmotion)
Specs give mono band style results by changing element
lengths to suit frequency of operation.
Having piddled many years with this approach using wire
inside fibre glass fishing poles I was never able to get
monoband specs with fixed element spacing.
Is it possible to get good specs on a fixed element position
and boom by just changing the element length without phasing
or the addition of varying loads and without a tuner?
I am aware that glass fibre enclosed elements provide for
shorter radiators but I am just curious as to what the
other variables are involved other than varying the element
lengths.

Well today finally got warm enough. I took the outer cover off the
BB3 and found that the finger stock was unsoldered for about 1/4 of
the circumference. May have pulled it loose when I did the driving
into the garage without removing the whip trick. I didn't think I was
ever going to get out from under the garage door. Looks like a trip
to the factory.

> Vito

I *have* tried it, and seen others who also have - and have YET to see such an "invisible" antenna
supported mere inches above an RV roof - metal or otherwise - that would perform as well as a
mediocre standard monoband mobile vertical!

Again I use/have used hamsticks, screwdrivers, hustlers, Master mobile, and frequently use an SGC
computerized autotuner with random length endfed "invisible" wires...

When I am fortunate enough to be in a more wilderness or lightly populated CG, the SGC and random
wire are great - but not too practical to be seen skulking thru CG underbrush with a
slingshot/spinning reel trying to shoot a line into a tree when it's crowded and cramped... So,
then, the various compromises come into play... and the absolute WORSE of those, is usually some
wire or loop antenna supported just above an RV or vehicle roof...

After bragging about how my BB3 has operated for 7 years without a problem, this morning I found the finger stock unsoldered for about 1-1/2" and moving up and down with the coil. No wonder I couldn't get it to resonate. Guess it will be going back to Farmington.

2547. Re: Newbie question: So why is my coax feed line radiating?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-04 20:46:13 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C5EF315.9CC2622B@eznec.com>
Source record: 149184

Coax doesn't have a "third conductor" any more than twinlead does. The currents on the two conductors of twinlead can be mathematically separated into differential mode currents, which are equal and opposite on the two conductors and cause no radiation, and a third, common mode current which is equal and in the same direction on the two conductors and does radiate. In a coax, they're physically separated, with the currents inside the coax being pure differential currents and the current on the outside pure common mode. But the effect is exactly the same.

Feeding a dipole with twinlead doesn't at all guarantee balanced currents on the two conductors. Unless you have a truly balanced tuner or a balun at the rig end, exactly the same spillover effect will occur as with coax. It'll just happen at the rig instead of at the antenna. The result will be unbalanced currents on the twinlead conductors -- that is, the presence of a common mode current -- that will radiate just like the current on the outside of a coax feedline.

It's really very simple to measure the current on each conductor of a feedline and to measure the common mode current. The method is described in "Baluns: What They Do and How They Do It", in the _ARRL Antenna Compendium_, Vol. 1.

Yes, any time an impedance is a signficant fraction of a wavelength long, it shoud be modeled as a distributed load as you've done. I tend to use small ferrite toroids for my baluns, which are physically short. They also have a resistive rather than inductive impedance, so I model them as a single fixed resistance.

Your matching system is fine. If I were you I'd simply wind some of that coax through a large ferrite core, 5-7 turns or so, near the antenna. Or string a half dozen or so cores over the outside of the coax. Type 43 ferrite or similar would be about the best kind to use, although 70 series would be fine too.

Certainly can optimize the element lengths based on the fixed positions of the elements. The F/B and gain will shift as freq. is adjusted....not a huge issue. The concept is good, the practical applications have been attempted in the past and the guys in Washington seem sincere with the offering of a unique yagi. The composite glass element tubing would be of more interest/concern in the electrical and UV properties areas. Of course if the PIC goes and/or the servo's loose sync, it would pose a major problem. Moving parts usually wear and are more prone to failure than static ones.

Bandwidth isn't an issue since the element length is adjusted for unity at whatever freq. you choose.

Download a copy of YagiMax or Elnec Demo and play with element lengths. Monitor the effects on pattern changes. You'll get a grasp of the gain and F/B shifting as the freq changes but not element positions. Pretty minor in most situations providing minimal spacing is met (and 18 foot boom does that).

Bests,

Patrick

2555. Multi frequency monoband antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-04 21:45:19 UTC
From: aunwin@fgi.net
Message-ID: <c4becf19.0202041345.2d68de22@posting.google.com>
Source record: 149194

After reading about "stretchable antennas
(fluidmotion) I tried to model a three
element beam on a 18 foot boom for multi
frequency use using AO with element length
being a variable.
I did not take into account element shortening
because of dielectric effect (fishing pole support)
but I could not find a fixed driver position that
would provide mono band performance from 20 thru 10,
either in practice or in the fall back position of
faulty computor use.
Anybody have any insight as to what the fixed driver
position should be,and of any other variables that
should be taken into account such as using coax for
elements or folded elements?
(I also tried driving one and all elements
even tho it couldn't then be called a yagi !)

I need something I can set up in 2 minutes, not string ropes or wires anywhere (Campground rules etc) and minimally obtrusive. The screwdriver fits that bill.

Dal, Dan:

Youse guys gotta hang around here more.

And mebbe... try a little harder to become NG "saints" yourselves, heh, heh...

BTW... young Jason, God love him, gets plenty of help from this particular NG crew, he has in the past, and he will in the future.

But you misjudge him, Jason is one of the *BIG* experts around here. Go have a look at his www site, and see.

He has set up there as a teacher and and all around "factotum", he has lots of tutorials and white papers there for anyone to learn from.

Go see for yourselves... BTW... the stuff on Jason's site is worth exactly what you pay for it... and...

BTW... whatcha get on this NG's is also free and worth exactly what you pay for it!

Got a problem with that?

Best,

--Peter K1PO

Hello everyone,

Just a note to let everyone know that we have new specials up for our Internet customers on the website. Here are the current specials:

http://www.sauderelectronics.com

__Pack of 10 Silver Teflon PL259s__
Pack of 10 Silver teflon PL259 with gold tip for RG8 coax (accepts reducer for smaller cable).
* ONLY $8.00 *

__3 ft. RG8X Jumper w/PL259__
$1.00 off 3ft. RG8X jumper cable w/PL259 connector. American made w/95% braid. Reg. $5.00.
* NOW ONLY $4.00 *

__SMA Dual Band HT Antenna__
Dual Band antenna for SMA handhelds. 2M and 440MHz antenna fits the newer handheld radios like Yaesu VX-5 and many others requiring the SMA type connection. Very flexible.
Regularly sells for $14.00.......now ONLY $12.00!

PLUS A FREE GIFT with any order over $25.00!!

No one beats our prices on accessories and connectors!

Thanks for looking,

Sauder Electronics

AHHhhhh - another "I don't RV very much" response - fact IS, MOST current "RV campgrounds" aren't
much but parking lots with landscaping - and MANY don't even add the landscaping!

The best RV CGs we use are the remote, wilderness type - no hookups, and few frills, but more room
and "natural" surroundings. But for those expecting or demanding full-feature CGs, expect that you
will ALSO get the crowding and lack of privacy that goes WITH it... Modern CGs aren't really geared
for use as a "final destination", but rather just a place to stay overnite, or while you then drive
to the REAL nearby attraction you came to see...

2568. R & X for simple antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-04 23:02:56 UTC
From: Jim Weir <jim@rst-engr.com>

Let's presume some simple antennas --

a rod or whip of finite diameter over a theoretically infinite ground plane

a simple dipole of finite diameter far away from any conducting earth.

What are the simplified formulas for calculating R and X at the feed point of these antennas, factoring in the finite width of the elements? If this is posted on a website somewhere (the actual formulas, not the formulas hidden inside a file) a pointer to the url would be most appreciated.

(I know I've got these formulas around this pigsty somewhere, but I've been looking for four hours now without finding them. Neither Krause, nor Jasik, nor the MIT RadLab series are particularly good sources of information on simple structures.)

Not true. In fact I spend a LOT of time in campgrounds and prefer
rustic campgrounds as opposed to concrete slabs in a row.

Campground owners will NOT allow ropes, wires in trees, and elaborate
antenna setups. They will allow a sat TV antenna and a "CB" antenna
(my screwdriver) looks like a CB antenna to them.

Mark

Hi Ed,
I'm no expert but I'll give it a whack as I understand it. Your ground should definitely be as short as possible. That's easy enough. I believe the electrical code dictates that there should be only one ground system in your home. I have heard that things like grounding to a pipe or the grounding post in a wall socket can cause problems. Piping might not be metal all the way down or could make a pathway that you've not expected or intended. For example, what if somewhere else the same pipe is grounded by the existing system? In my opinion, you might consider any extra length to run a ground to the rod(s) used in the house's existing system. The issue as you probably already know is that an above ground, ground wire could be resonant and act like an antenna, causing QRN or (worse) bringing that energy back at you in the form of mic burn. Somebody correct me if I'm wrong or elaborate if my explanation is a little confusing.
Now for the ground buss. When folks say, "don't daisy chain" your equipment, they mean to avoid a ground loop. Your ground strap/wire may be connected to a bar or plate so as to make it easier to make multiple connections to it vice a single, tiny wire that's expected to handle a current that may be too much. Up to this point, you've got a simple rod>wire or strap>buss. Now, you should run an single ground wire/strap from each piece of equipment to the buss. This way, each piece of equipment has it's own path to ground.
Example: xcvr > buss, tuner > buss, controller > buss, etc.
You can see that each piece has a simple path to ground and, taking the path of least resistance, doesn't want to effect everything in your station. The ground setup is like an upside down tree with the roots as ground wires from each individual piece of equipment and the tree top is the ground rod. The daisy chained setup (bad) is where you'd hook these things in series and might look like this:
power supply > xcvr > tuner > controller > etc. > ground
What's gonna happen if the xcvr needs to go to ground? Bam! You guessed it, through the tuner, the controller, the etc. because it might not have any choice. Of course, the longer path and other factors might even make your hands on the mic a more favorable path to ground exiting through your feet (though not likely since you're on the second floor). This kind of "round robin" circuit should be avoided. It's also possible to unintentionally make this kind of deal if you're grounding through the grounding pole of a light socket. As a rule of thumb, try to plug all your equipment in to the same circuit in your house (i.e. don't plug a power supply in to the garage, and the xcvr in to an outlet in the office.
When looking at grounding paths, I try to see all the avenues thinking of them as water pipes that water can flow both ways through. You'll hear a lot of the more knowledgeable hams explaining the myriad of ways current and RF can find a way into your shack and some of them are really surprising

since we don't think of them inside our little warm box. One of the most interesting ways I've heard in a long time was a lightning ground strike that actually was believed to have entered through the ground wire and exited (I think) though the power lines damaging the ham's rig in the middle. That's obviously outside our normal paradigm:)
Based on the length of my reply, chances are that I've said something wrong or possibly confused an issue. That's sure to draw another post:)
Haha! Anyway, I hope this helps you to draw closer to the creamy center of ham radio:)
Best Regards to ya Ed,
Drink, WP3JQ

And, shortly later, discussing twinlead feedline:

"However, when we connect the rig to ground, . . we've again provided a
third conductor in parallel with the right side of the feed line, and
the same problem occurs as with the coaxial cable."

In both the article and my postings I'm trying to convey the fact that
the type of feedline -- coax or twinlead -- doesn't determine balance or
radiation. Coax can be balanced and twinlead unbalanced.

Roy Lewallen wrote:
"Coax doesn`t have a "third conductor" any more than twinlead does."

Wrong. Coax has an insuleted center conductor. Coax has an inside surface of its shield. Coax has an outside surface of its shield. The voltages on all three of these conductors is usually different from each other.
Skin effect isolates the inside surface from the outside surface of the coax shield.

Quoting from the underused ARRL Antenna Book 19th edition page 26-4:

"Stated briefly, the unbalance with coaxial line is caused by the fact that the outside surface of the outer braid is not coupled to the antenna in the same way as the inner conductor and the inner surface of the outer braid."

There is a phase difference caused by the difference in velocities of the waves traveling inside the cable and traveling outside the cable.

Then there is the infamous Fig 24 on page 26-16 of the ARRL Antenna Book, which is worth 1000 words.

Best regards, Richard Harrison, KB5WZI

"Suffer", "discomfort"... I remember when I took a course in ham-radio as well as the lessons in Morse code, even though it's been 24 years now; my experience has been an enjoyable one, so I am sorry, but I can't relate to your pain and suffering. By the same token, shouldn't we eliminate any testing because it causes discomfort to some people? After all, electronics theory is a necessary evil from the time factory made rigs and antennas were not being made.

What third conductor with twinlead? What you see is what you get.

A balanced circuit is balanced at both ends. In the case of twinlead connecting a sender with a balanced dipole, the sender must be balanced and the balanced line must remain balanced enroute. OK, conversions to and from unbalanced segments can be made enroute, but that`s another issue.

There is no third conductor in twinlead. Common-mode current is shared on both conductors of twinlead.

A good point. There's an exactly analagous situation between the differential and common mode currents on a two conductor line. They also propagate at different velocities. Like the differential (inner) and common mode (outer) currents of a coaxial cable, the differential mode currents propagate more slowly than the common mode current, since the differential field encompasses more dielectric.

Dear Ian,

On the same thread -

At this juncture I am severely tempted to say I am laughing my head off at the reams and reams of mental contortions, and the enormous extent to which some people will go to evade admitting they havn't understood what they have been preaching about for years.

But I won't. ;o)

Point 1. As you have no idea of the power radiated from the braid of a coaxial line when it is feeding (wthout a choke) the centre of a 1/2-wave dipole, the remainder of your arguments carry no weight.

Point 2. The only person on the right track was Cecil when he asked what's the input impedance (seen looking into the top end) of the coaxial braid when the braid is 1/2-wavelength long and is grounded at the bottom end. (Actually, it's a function of the radiation resistance.)

Regards, Reg, G4FGQ

Humm,

Well I could use say 150 Ohms resistive and 150 Ohms reactive for the
loads that would roughly equal 250 Ohms impedance for each load.
Which, as you suggest, could be more accurate. That sould better
approximate ferrite beads have the Q of 1. Will get around to it and
see if there is any noticeable difference in the results.

My thinking at the moment is that a string of beads are a little
easier to do than making two toridal wound baluns. But no big deal
ether way.

Ed Strungis wrote:
"---most sources call for a ground run to be as short as possible."

Good advice.

"Also some sources say multiple ground rods, about 8 feet apart bonded together."

More good advice, as paralleled connections have lower impedance. NEC requires all ground connections be bonded together. The purpose is to minimize the potential difference between ground connections.

The separate ground for your shack is to prevent lightning current involving your antenna system producing a large voltage drop across household grounding wires and the appliances connected to them.

It is advisable to have a separate shack ground cable to the ground connection for your electrical service.

You should have a ground connection outside for your outside antenna system. This ground must also be connected with the electrical service ground point, be it metalic water piping, ground rod, or both.

The aim in grounding is to avoid potential differences between grounded objects. Voltage drops across pretty small impedances can be large when huge currents from lightning are involved.

If everything has its own short wire to a common groundpoint (the electric service ground) there is small chance of a large voltage difference between these things.

Unfortunately your house wiring isn`t usually done this way. Those electrical outlets are usually daisy chained. Salvation is in the short distances involved and in the limited exposure of the connected devices to lightning. A ham rig is not in the same category as an electric clock.

I have an MFJ1026. It works for removing the constant noise for the commuter rail nearby. What it won't do is remove things like thunderstorms and other annoyances associated with life. In other words if you have a source that you can pinpoint, it can likely make receive bearable by nulling out the noise. I'm told the apparently no longer produced ANC4 works pretty well, but the MFJ product is still available and works for me. It's not perfect, but it does allow me to get on HF and hear folks that I otherwise would not be able to.

Yes. It is a function of the radiation resistance, but a 1/2-wave grounded vertical antenna may have a drivepoint impedance of about 700 ohms.

I stand corrected. There is not a low impedance on the outside of the coax at the drivepoint as I mistakenly said.

It finally dawns upon me why I`ve gotten away with not using baluns with countless installations of coax feeding balanced dipoles with apparently no ill effects.

I appreciate the relevation.

>> What is best Mobile Hf Antenna ?

A very broad question. But from the radiating efficiency and long-term durability, reliability point of view the best is what you pay the most money for. (Unless you are one of those unfortunate people born every minute who have never bought one before.)

If you want to barter money for time then make your own antenna. You will also gain more satisfaction, suffer less agro, live a more contented life, and so prolong longevity.

Furthermore, your family, friends and associates will participate in the benefits of you being easier to live with.

I wish you the very best of mobile DXing but don't drink and drive otherwise the other fellow will be wondering why you suddenly switched off.

That's the attraction of a string of beads -- it's easier to implement than a toroid, especially with large diameter coax. It also provides better heat dissipation if that's a problem. The disadvantage is that it takes a lot more ferrite to get a high impedance. 5 turns around one core gives you as much impedance as 25 cores strung along the coax (assuming comparable magnetic cross section/path length ratios).

Hi Richard,

The third wire is going to ground, not up into the sky. In an
unbalanced output, the right side (as I understand it) is equipment
ground which has inherited a wire in parallel at the drive point (not
physical parallel).

New book due out next month:

Cylindrical Antennas and Arrays

King, Ronold W.P., Fikioris, George J. and Mack, Richard B.

In general, if you can find works by Prof. King, they are likely to
have what you want. An introduction can be found in King, Mimno and
Wing, "Transmission Lines, Antennas and Waveguides," not surprisingly
in the Antennas chapter. There _is_ a formula there, but you might
not like the form it's in; but there are lots of useful graphs in that
chapter. Prof. King was certainly one of the leaders in understanding
linear antennas, and I suspect many would put him above all others in
that area. I personally have a lot of respect for the clarity of his
writing.

Cheers,
Tom

Richard said -
> I appreciate the relevation.
==========

Economics always wins in the end.

Unfortunately Economics is a much-too-neglected subject in the modern Western engineer's training and education.

When George Stevenson designed the first steam locomotive to draw passenger trains, the Rocket, around 1825 he took into account the cost of coal and the expected price of railway tickets-to-ride.

But, like you, George was fortunate his first design did not explode with a burst boiler during the first competitive trials.

Same applies to chokes in feedlines. If it works, don't fix it.

Incidentally, the very first passenger train to run ran over and killed the member of the Westminster parliament who had been invited to officially open the railway passenger line from Rainhill, near Liverpool, to Manchester.

He stood in the middle of the track in front of the engine and said "I now have the great pleasure of decaring this very first passenger railway line open" and waved a green flag followed by blowing a whistle which was the last thing he ever did of his own volition.

In this emergency the engine was uncoupled from the passenger coaches containing the Lord Mayor and Dignatories of Liverpool and the unfortunate member of parliament was conveyed in the engine cab to a hospital near the railway line at Eccles near Manchester.

Although the engine broke the then-existing speed record it could not be included in the Guiness Book of Records because it was not drawing any wagons or coaches at the time.

The member of parliament was pronounced DOA at the hospital. But he did get into the records as the very first person on Earth to be run over and killed by a scheduled passenger train. There's a statue to him somewhere whereas, otherwise, he would probably have been forgotten..

Another severely neglected subject in the modern Western engineer's education is elementary statistical analysis. Some bright young things are actually proud of their declared ignorance of what, if they took a little trouble to discover, is itself an essential source of beautiful, reassuring engineering design tools.

Aloha, anyone got any suggestions for soldering weathered stranded wire? I'm trying to revive my G5RV which blew down during the last storm here. I've tried wire brushing it, sanding it, using flux...none of these work. Is there some homebrew secret for cleaning corrosion from copper wire, making it like new so it can be soldered? Some acid wash or something? Mahalo, I appreciate the help.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-05 07:27:17 UTC
From: Rick Karlquist <richard@karlquist.removethis.com>
Message-ID: <pPL78.23345$Ri2.75328@rwcrnsc54>
Source record: 149236

FYI

I have posted a description of my 7 element electrically steerable

vertical phased array on my web site: www.n6rk.com

at the following URLs:

http://www.n6rk.com/7_hex_array.pdf

http://www.n6rk.com/driving_the_7_hex.pdf

http://www.n6rk.com/7_hex_eznec.html

It has 8 to 9 dB gain over an individual vertical and can

be aimed in any of 12 directions. A 40 meter version has

been put on the air, and an 80 meter version is currently

under construction. It occupies a hexagon 3/4 wavelength

from vertex to vertex.

Years ago I had a paste that you would dip the wire into and then remove it with an industrial wipe.. From the way I remember it stinging if you got some on your hand it was acid based. I'm not sure how good an idea it would be to use it on stranded wire but it worked great for removing varnish off solid wire when I worked doing electronic assembly and had to wire transformer leads to a circuit board.

I suspect some would cringe at this but I'd probably try a bit of diluted pool acid (HCl - muriatic acid) and then wash it well with water and dry it. I think rubber gloves and eye protection would be a VERY GOOD idea if doing this.

Aren't you glad you don't live in Southern California? In case you need a little more justification, here are some excerpts from my association's Declaration of Restrictions:

"This Declaration of Restrictions made this 12th day of March, 1940, by Rancho Santa Anita Inc., a California Corporation,..."

"1. No part of any of said realty shall ever be sold , conveyed, leased, or rented to any person not of the white or Caucasian race.

"2. No part of any of said realty shall ever at any time be used or occupied or be permitted to be used or occupied by any person not of the white or Caucasian race, except such as are in the employ of the resident owners or resident tenants of said property."

The document goes on to list all of the prohibited structures and actions, and then this:

"11. If at any time any of said paragraphs numbers 1 to 10, inclusive, or any part thereof, shall be adjudged or held to be illegal or invalid, such illegality or invalidity shall in no wise affect or render illegal or invalid any of the other terms, conditions, covenants, and restrictions of said paragraph, or of any other paragraph or part thereof, but each and all of said other terms, conditions, covenants, and restrictions, notwithstanding said illegality or invalidity, shall be and remain in full force and effect."

How do you like that?

I know what I would do. I would get a Ham 440 MHz antenna - then trim it
to work on 477 MHz.

A many element design would basically be just extra directors added to
a design with only two or three directors.

Wire brushing to shiny copper should be sufficient - as should sanding.
The problem may be the solders they sell these days, that contain little
or no lead.

You might try talking to a plumber, and see what they use - although
their fluxes may be acid, which you really wouldn't want on an electrical
circuit.

I have several pounds of 60:40 tin/lead solder. I have never had any problem
soldering copper with it, even copper that has an oxide coating.

Actually, I have a very good idea. I've measured coax surface currents in real life, wherever the coax is accessible to clamp a probe on, and modeled a number of situations to understand what happens up there where I can't reach. (Have you?)

Not surprisingly, feedline surface currents can vary a lot, but they can often be a significant fraction of the main "antenna" current (tens of percent). If you're happy with possibly tens or hundreds of milliamps of RF on the coax surface, flowing off to cause trouble who-knows-where-else, then so be it. I'm not.

>Point 2. The only person on the right track was Cecil when he asked what's
>the input impedance (seen looking into the top end) of the coaxial braid
>when the braid is 1/2-wavelength long and is grounded at the bottom end.
>(Actually, it's a function of the radiation resistance.)

Go on, I'd never have guessed... We know that some antenna/feedline situations are worse than others for surface-current effects (coax) or common-mode effects (twin-lead), and we understand why. That knowledge is almost as old as radio - the "Marconi Effect" in doublet antennas" - and Roy's classic article demonstrates how it works.

But that isn't the main problem.

The main problem is wishful thinking on the part of amateurs when we use the word "balanced"... as if it was a magic word that would make all our problems go away.

Here are some unpleasant truths:

1. There is no such thing as a perfectly balanced antenna-feedline layout. It is an ideal that only exists in your head. Zero surface or common-mode current is only achieved when two large antenna currents are exactly equal and opposite - and that doesn't happen in real life.

2. Antenna/feedline systems don't "want" to be balanced. There is nothing in Nature that pulls them towards a balanced configuration. You have to shove them, and they'll often fight back.

When we talk about "balanced feedline", that's all it is - just talk. Talk and wishful thinking don't make it happen.

3. Coax will happily support surface currents; most of us know that. Twin feeder will equally happily support both differential (balanced) currents and common-mode currents - but most of us don't know that. We tend to call it "balanced line" and believe (wishfully) that naming it makes it true. It isn't.

4. What we can do, is to *force* the situation more towards the way we'd like it. We can force coax surface currents down by using a choke, and force common-mode currents on twin feeder down by using a balun at the transmitter end (we can also choke common-mode currents on twin feeder, but that's more rarely done).

5. Whatever we try, if the antenna/feedline layout is physically unbalanced, it will fight back to keep those unwanted currents flowing. The best we can do is force those currents down below the level where they cause trouble (and that also depends on our power level - the more power we use, the harder we have to work to keep those currents down).

6. "Physically UNbalanced" applies to every antenna you can ever build. This includes:

a) Any antenna fed with coax, because the feedpoint is fundamentally asymmetrical. One side of the antenna is connected only to one conductor (the center conductor). The other side is connected to two conductors: the inner and outer surfaces of the sleeve.

A coax-fed antenna can only ever be "near-enough balanced", or "so close to balanced that the difference doesn't matter"... but don't ever believe that it is truly balanced, because it fundamentally can not be. If you don't actively choke surface currents to prevent them from flowing, they *will* flow.

b) Any antenna that has deliberately asymmetrical wires (off-center-fed types being the obvious example).

c) Any antenna that is in asymmetrical surroundings - in other words, *all* real-world antennas! For example, you can make a horizontal dipole with exactly equal leg lengths, but if one end is close to a house or a metal mast and the other end is not, the surroundings are asymmetrical so the antenna will be unbalanced.

Once again, the surroundings can only ever be "near-enough symmetrical", or "so close to symmetrical that the difference doesn't matter"...

because the world around your antenna is not in fact perfectly symmetrical.

d) *Every* vertical antenna - because every vertical is asymmetrical with respect to ground. The same applies to antennas that slope with respect to ground.

The only differences between cases a) through d) are the degree to which each particular system is UNbalanced.

I'm sorry for those bucketfuls of cold water, but it's important to understand that a balanced antenna has as much reality as the Tooth Fairy. Fortunately we understand the Tooth Fairy a little better: we know that unless we do a few small practical things to help the magic along, she isn't going to call.

In the same way, understand that your antenna won't be anywhere near balanced unless *you* do a few small practical things to make it so. If you don't, the Balance Fairy won't call.

Plumbers flux is acidic, some more than others (IIRC eutectic is the
nastiest one) but all are neutralised by water.
I too have experienced problems with corroded copper aerial wire and I
tried plumbers flux, as I were one and had some old stock of the
stuff. It did'nt work no how, even when shiney clean. For some reason
the wire just wont tin, and yes I was using 60/40 I also tried
plumbers 'wiping' solder which is a slightly different melting point.
I've given up on trying and just waiting for the next rally to buy
replacement HD Copper.

The input impedance, R+jX, of a vertical wire above ground of height H and diameter D at any frequency F can be found directly by using programs ENDFEED, BOTLOAD and others. They are values which come out in the wash on the way to calculating (the primary purpose) more useful practical values.

Most of these programs include the effects of ground-loss resistance and RF skin resistance of the wire itself.

The feedpoint impedance of an isolated dipole is *exactly* double the value of a vertical wire above a perfect ground with height equal to half the length of the dipole.

Programs DIPOLE2 and others deal directly, as the name implies, with a balanced-about-ground dipole.

You seem to have had difficulty with finding R+jX. This is because the 'experts' and 'gurus', the book-writers, are usually academics, university profs, rather than practicing engineers. They don't appreciate what it is YOU want to know or why YOU should want to know it.

True engineers, dedicated to their work and knowing what it's all about, learning up to the very last minute, don't have time to write books.

To calculate the feedpoint impedance of an antenna it is necessary to mathematically model it as a transmission line with impedance Zo = Ro+jXo and to distribute the equivalent radiation resistance + wire loss resistance uniformly along its length. There is no simplified way of going about it. No simple formulas. There are one or two approximating short cuts.

But let's face it, you are not directly interested in Zin = R+jX. You only want to know Zin so you can select the values of L and C in the tuner and other practical values.

Programs ENFDEED and DIPOLE2, and some of the others, not only calculate Zin but L uH and C pF, antenna loss, feeder loss, tuner loss, ground loss, etc.

If you should ask from where I obtained the formulae incorporated in the programs, I worked then out for myself. If anyone should think from measurements any of them are in error then please advise me. I have done much checking myself. Results are more than sufficiently accurate for the intended purposes.

Download ENDFEED, BOTLOAD and DIPOLE2 from website below. Each is one self contained file. Takes only a few seconds. No unzipping inconvenience. Run and enter data immediately. No 2-week training course needed on program operating procedures.

> I am looking for some information on the LATTIN multi band dipole.
> Les, AA4F

Les.....the Lattin has been discussed here more than once. As far as I know, no one in this group has been successful in building a Lattin. I tried, several times....used up a lot of wire, but had confusing results......non-satisfactory results.

You might try searching this group using keyword "lattin" ......
You will get several "hits", and those hits, if read, will more or less summarize the efforts and interest of this group in the Lattin antenna.

I still wonder......if a knowledgeable person, using a combination of antenna modelling.....and one of those "Antenna Analyzers"......might that person successfully build a Lattin? I would sure like to see that happen. I have been intrigued by the Lattin antenna for a REAL long time.

>>> I am looking for some information on the LATTIN multi band dipole

The following is some of the info I gathered in my attempts to understand and build a Lattin. As I said in my previous post, I was never able to get it to work as Mr. Lattin described.

It has been patented, filed Feb 13, 1948. Patent # 2,535,298 My local library had the patent on microfiche, and I was able to get it copied. I have a copy of his patent, with illustrations/drawings, on file here.

Lattin described this antenna in QST in December of 1960.

July 1960 issue of "CQ" mag has a related antenna project, by Richmond, W1CEJ, called "A Portable Dipole"

Vincent Lear, G3TKN has also worked with the Lattin design, and was published in RSGB.

July 1992 issue of "73" mag has another article "Six-band linear trap antenna" by Brumbaugh KB4ZGC.....using approx the same idea.

September 1986 issue of "73" mag has Lattin type antenna project described...."The Texas Tango Antenna" by Garrett K5BTV.

Maybe the above info will stimulate some more experimentation with the Lattin. I sure hope so.

Richard Clark wrote:
"The third wire is going to ground not up in the sky."

That is reasonable. Wires to ground have no effect on balance if there is balanced feed to and from the transmission line and the balance is maintained enroute.

An example is found in the lack of hum and other noise in balanced telephone lines. Ground either wire and the noise is overpowering.

Best regards, Richard Harrison, KB5WZI

Hi Dave:

Had the same situation with my Ford Explorer and put a little "G.I. Ingenuity" to work and have developed an answer to the problem. This mounting bracket works well, with a 13" Comet ant. I can get in/out of the garage, and will be ideal for "Leased " SUV,s (where visible holes are a no-no!). It will be custom built for individual makes/models, and will handle longer ant. if garaging is not a concern. Best of all, when finally removed, there is no easily detected sign it was ever installed.
If you're interested , e-mail me direct.
Regards
Bill

One nice feature of a string of beads is that it is unobtrusive.

BTW, can you point me to a source of information about which beads I
should use on RG-8X (I think F73-801) and how many (or what length) I
need for a broadband choke?

Ian, G3SEK wrote:
"When we talk about "balanced feedline", that`s all it is - just talk."

For practical purposes they are balanced. I worked for years in a commercial shortwave broadcast plant. We had miles of 600-ohm oper-wire lines. A dozen high-power transmitters fed a cross-bar switch arranged so that any transmitter could use any of dozens of balanced antennas. We never had five minutes trouble with imbalance.

Ian is too pessimistic.

You may well be right. But even if that is true, those who 'can' deserve the opportunity to 'do' and thus to contribute their individual 'best' to our society and country. That's what made us #1 in the world. Assuming that any one person cannot do something well just because most cannot has the effect of throwing that persons potential contributions away unused. We barely beat Germany to the A-bomb thanks to a handful of individuals. If any one of them had been denied the opportunity to contribute ... :o(

And as far as mixing goes my advise is get used to it. Our lives are too short to waste worrying over things like that. Besides, it might be the best thing. The whole problem goes away if everybody is tan :o).

Should not make any difference....

Good Luck!
73 de V.

>
> While I'm at it, any other pointers on this kind of antenna?

Nah.. You should be aware that if You win something (space) You lose
something else (efficiency). Radiated power will be less than from a
dipole.

Neat!!!

I actually thought of this idea many years ago, but never got enough 'roundtuits' to actually do it. My hat is off to you, Rick!

I have a keen interest in phased arrays, since I did my MSEE thesis on one. It had 6 elements in a circle and was for receive only. By using DSP algorithms I could form a 'image' of the radio environment---essentially creating many beams all simultaneously.

In response to some statements on your web site FAQ....Yes, you can use parasitic elements. There is no reason why they have to be in a straight line. The easiest way would be to have them all be the same length and put a reactive element at the bottom for tuning. In fact, I have worked out a design in Elnec where you can feed guy wires as parasitic reflectors. Again, I do not have enough roundtuits to pursue it further, although I did install my present guys with this in mind.

Again, congrats on a great idea!

This thread reminds me of the time a couple friends and I took a pop-up down
to the NC
coast for a weekend of fishing, swimming and visiting the battleship USS
North Carolina.
We selected a minimum facilities CG near the mouth of the Cape Fear river,
and after a
Saturday of doing all the above, we were tired out. About 2 in the morning
we were awakened
by a "scrunching" sound as if something was rubbing , or being dragged,
along the ground. We
got up to investigate and were greeted with the sound of deafening diesel
engines being run at
high RPMs. It was a float of barges and a tug that had run aground in the
river. The tide had
gone out, and the skipper picked the wrong time to go upriver! We waded out
into the river,
and the water level was so low we waded to within 10 feet of the tug! They
were shining spot
lights all around, I suppose, to gauge the depth and to see how badly they
were grounded. The
light passed across us, and did a "double take", stopping right on us.
Within a few seconds, the
diesels idled down to a contented purr. A deckhand asked us if we waded or
swam out, and we told him we merely walked out there. Someone in the
background swore a little, we stood
around for about 15 minutes and then waded back to the shore. We slept
soundly, and when
we awoke Sunday morning, the tide was back in and the tug was gone.

Sanding or wire brushing down to bare copper should be enough. One
thing to avoid is acid-based flux on stranded wire. The acid will wick
between the strands and will be near impossible to remove completely.

Picture what will happen with acid trapped between the strands over a
period of time. :-(

Ken wrote:
"Well, I can`t say that the light has gone on for me too,---."

The current traveling on the inside surface of the coax outer conductor has two exits and divides between them depending on their conductivities.

The quarter-wave half-dipole is one of the exits. It is open-circuit at its far end but doesn`t appear infinitely conductive, 1/4-wave back at the drivepoint, because of its imperfection as a transmission line. It is radiating. So, it looks as if its resistance is about 1/2 of 75 ohms.

The half-wave coax exterior is the other exit for interior coax sheath current. Its acceptance of current also depends on the conductivity it presents. Although the 1/2-wave exterior of the coax is grounded at the far end as seen from the dipole drivepoint, it doesn`t look like a short-circuit because of the imperfection of the coax exterior as a transmission line. It too is radiating, however small the amount. Fact is, while impedance presented by the dipole may be 10s of ohms, the impedance presented by the coax exterior may be 100s of ohms. So, most of the current and radiation is on the dipole and little is on the outside of the coax.

Best regards, Richard Harrison, KB5WZI

2628. Re: What is best Mobile Hf Antenna

Hey Dick,

I still have 3 of those old 75 meter Master Mobile coils and one original 3' Master Mobile mast! Two of them are just like new with the MM logo still on them. As you know, at one
time HF mobile kind of fell by the wayside back in the 70s. You could pick up one of those
MM coils for a buck or 2, so everytime I saw one in a 'junk' box, I would pick it up just for
a keepsake. I bought my first MM coil in l966 and literally wore it out.

My first HF mobile experiences were gained thru Civil Air Patrol, and, at the ripe old age of
18, I had a Lettine 240 (about 40 watts), the requisite HV dynamotor, and a receive converter
in a 1967 Chevrolet coupe. I knew zilch about radio, and my "git-out" ability reflected it! But
those early mistakes made a foundation upon which to build, and now I can do a pretty decent
job with mobile DX. I learned really quick about accidentally leaving my filaments on because
that little caper would suck your battery dry in a heartbeat! Hey, I could go down the road at
night, key the mike, and dim the headlights better than using the foot dimmer! LOL!

Incidentally, since you brought up Master Mobile, I wonder what happened to them. I know they folded (early 70s?), and I was just wondering if someone still held "rights", proprietary, and
name rights to MM. They made some pretty good antennas in their day.

I finally "went and done it"! For those looking to buy screwdriver
antennas, I would like to invite you to visit my website at
www.qsl.net/k4kwh! After a long reluctance, I was talked into
it by a most kind gentleman who helped me get the site up and running.
Please drop by and give the Carolina Cyclone products a look.

Tnx and 73

Jerry

Ken wrote:
"It doesn`t matter if your feedline radiates a bit."

That is true so long as feedline radiation does not produce interference such as TVI, r-f bites and burns, or unpleasant feedback effects in your equipment.

Best regards, Richard Harrison, KB5WZI

Thanks for the info Gary but in theory a resonant horizontal dipole at
say 13' otta outperform a hamstick with its tip at the same height.
Parking a nonmetallic MH under the dipole shouldn't make much
difference. What do the antenna models say?

The original post was about replacing a more or less permanently mounted
screwdriver that'd been damaged by weather. For that application, we
agree a wire and tuner would be more efficient than a screwdriver. I
sincerely grieve for the children in Etheopia, No. Korea, and for others
even less fortunate, including those forced to use crowded CGs. I'd
rather stay home where I have more space.

Thanks for responding Patrick
First, apologies for the repeat posting

I am sure that the designers are sincere
but I was weighing their experiences against my own.
I know that fishing poles can handle the uv and the ice storms
in Illinois, the taper and the flex works just fine.
But when I did a simiar thing using a combination loop
dipole elements where the capacitor was tuned using an
AEA automatic loop tuner I felt that I was obtaining
unity because of the antenna SYSTEM not just the antenna.
(I was able to remove T.V.I by retuning)
I chose the capacitor varing to reduce moving parts and to get
the higher gain at the higher frequencies using the longer
elements (see Moxons book)
But I was not convinced that the feed was not part of the antenna.
Same way with the varing wire lengths inside the fishing poles.
(As I stated earlier the fibre glass greatly affected the element
lenghts and adding to my concerns)
It is for that reason I was looking for the required spacings
since my lousy modelling using the excellent AO program with
element lengths varing did not supply acceptable spacings for
reasonably equal impedances at the antenna for the 14 thru 10.
(bad modelling!)
The tuning of the elements did help for 40 and 80 by allowing
the coax (antenna system) to radiatiate and get on those bands.
If some one could let me know the driver spacing on this
new antenna (fluidtronics) I would really appreciate it
since I, with my setup, was not comfortable without a external
tuner at the antenna
Art

PS
For those who are interested in telescopic fishing poles as
elements they are much cheaper than aluminum and I have also made many
using alum foil on the outside surface
($2 each when buying direct from China and most fishing stores
would be eager to sell same less than retail, approx $10)

Reg is always saying that unless you can express what you are saying in numbers----.

OK. By law, our overall signal to noise ratio had to exceed 50 db. Not bad for open-wire lines on poles. It indicates the common-mode trash in the wires was enervated by line balance
(equal currents in opposite directions through the loads).

Best regards, Richard Harrison, KB5WZI

"IIRC eutectic is the nastiest one"

Eutectic is the combination of tin and lead with the lowest melting temperature. It is only slightly smaller than a 60/40 ratio.

How well solder takes to metal depends on the flux and its distribution. Acid flux cleans the surface to be soldered much better than rosin flux but must be neutralized or removed to avoid subsequent corrosion.

Hi Richard,

You don't go far enough. Especially when you have, I believe, a copy
of LaPort nearby. I've seen power line engineering manuals and
observe they "twist" their line on a regular basis to maintain
balance. I would presume LaPort treats this topic (the one compelling
remembrance of a copy passing through my hands was his treatment of
power distribution). Your 50 dB spec wouldn't be obtainable
otherwise.

Wide spaced lines that run parallel through a field are a prime target
for induced currents.

You might be surprised at the number of "RVers" who plan entire trips around the availability of
Walmart and Flying J parking lots... Funny how they manage to come up with 50 grand or so for an RV
setup - yet can't seem to afford a place to stay that's designed, zoned and established for overnite
stays. THEY like to claim they're "thrifty" - *I* think they are just plain CHEAP! RVers entering
the lifestyle and expecting free parking really aren't much different than a fella getting a ham
ticket - THEN expecting someone to provide them a free station to operate with...

If ya can't accepy and afford the associated expenses of the lifestyle, better take up stamp
collecting or needlepoint...

I can only help you out with general information. A type of ferrite that's most common and a good compromise to use for HF is Fair-Rite type 43. Other manufacturers offer similar products. Someone else can probably give you some specific recommendations, or you can visit the Fair-Rite or Amidon web site. Locate cores with large enough inside diameter to fit over the cable. Look at the impedance vs frequency data for the cores and get enough cores to provide at least 500 ohms (1000 might be a bit better) of impedance at the lowest frequency you intend to use it at. All else being equal, longer and thicker cores will have more impedance per core. I think the Wireman and probably other vendors sell kits of cores. I recall seeing some impedance values from Amidon that seemed awfully optimistic, but I haven't measured any of the cores in question to see whether they really are.

If you're running over a kW and/or running a high duty cycle, you might need to replace all or some of the cores with one of the 60 series ferrites to reduce heating. If you do that, you'll need more cores, since the per-core impedance will be lower.

>
> So does everyone who disagrees with you have a "serious character flaw" ??

I never said that. I said that people who think everybody should be forced to endure every hardship and disease they suffered have a serious character flaw.

I have a bad back. Hurts all the time! Does that mean everybody should have a bad back? Should I denigrate everybody who doesn't share my burden? Should the government break yours so it'd be like mine? I think not.

Kids my generation had to fear Polio because there was no vaccine yet. Does that make it unfair to give kids the vaccine now? Again I think not. Same goes for CW. There was a time when CW was the only practical way to communicate via radio. There was also a time when flint & steel was the only practical way to start a fire. People in those times had to master those skills. Should the law make us do the same out of "fairness" to them? I don't think so.

We might argue over whether everybody ought to learn code because it's so much fun without either of us having a character flaw. You could argue that Morse is needed for emergencies and merely be wrong (tap-code is more common), but not a jerk. OTOH the arguement that everybody should be forced to learn Morse because you or I had to learn Morse is selfishness at its worst.

A practical difficulty with using parasitic vertical elements is ground loss. You'll find that it doesn't take much ground loss resistance to pretty much lose any gain you'd get from a parasitic vertical that's a quarter wavelength high or less. It's less of a problem with longer elements, and none at all with elements that are close to a half wavelength long.

DUNNO about the "models" - or whether they even HAVE a program that predicts performance of
antennas
suspended above large structures - metal or otherwise - PLUS, the above original statement
was to a
wire "suspended JUST OFF the roof" - 13 feet or so is hardly "just off" - and *I* was
referring to
an antenna INCHES off, not FEET... And as already pointed out, such antennas I and others
have
tried, they perform quite poorly compared to other alternatives. Sure, some dwellers in
antenna
restricted subdivisions DO run attic antennas, and they WILL work... after a fashion... but
NOTHING
like a decent outside antenna in the clear at even a modest height.

I'm glad for you. I would like to be better at Morse than I am but it
has always been very difficult for me (see the article on that subject
on www.arrl.org) and "profound" hearing loss has made it worse.

> By the same token, shouldn't we eliminate any testing because it
> causes discomfort to some people?

Not as long as we are still licensed to do things that other citizens
are not, based on the idea that we're "experts". CBrs cannot legally use
high-powered amps and business licensees must hire licensed techs to do
the things we can do at will. We can legally modify our factory-made
radios to operate out of spec on the assumption that we are learned
enough to do so safely. CBrs (for example) cannot.

It makes sense to require a Morse test to operate Morse on bands set
aside for that purpose, but a Morse test to operate SSB? Oy!

2651. Re: Multi frequency monoband antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-05 19:01:02 UTC
From: aunwin@fgi.net
Message-ID: <c4becf19.0202051101.28d2adc7@posting.google.com>
Source record: 149135

Hi Jim
First may I apologise for the double posting.
It was the first time I had posted on this forum since before
Google came along. True to past form I tripped over my
own feet and double posted.

Discussing the pro's and cons of my description could well become a
pissing contest over time.
I do not see it as a contradiction of terms.

Many antennas like the 'tri bander' can operate on more than one
frequency
and I suspect the enterprising ham could also transmit on two
frequencies at the same time useing extra transmitters. Thus the term
"band" in its description
even tho it has a somewhat similar appearance to a mono bander
ie three elements.
There are many other three element antennas by appearance where the
appearance may appear the same but it has a electrical/mechanical
variable.
A combination loop/dipole is such an example. At any one time it is a
monobander albiet a highly selective pass band in some cases.
By use of this variable one has a monobander in appearance but with a
'floating' resonant frequency because of the addition of a variable.
ie multi frequency mono bander.
All the above is beside the point since I was asking a totally
different question unfortunately on two different postings.
Regards
Art

>Acid can be easily neutralized.

Acid can only be neutralized with alkali. If you get excess alkali, you have alkali in the strands. If you don't use enough, you still have some acid remaining. You can never get the balance exactly perfect and neither condition is desirable.

Best to avoid it in the first place. Thorough cleaning of the outside of the strand bundle followed by soldering with non-corrosive flux should do the job.

Well, Kraus is a pretty practical guy, as is Jasik, Roberts, Hamsher, and a
few other sitting in my library, but either I'm too dumb to understand what
they are telling me (entirely possible) or it is not an intuitive
calculation.

>
> True engineers, dedicated to their work and knowing what it's all about,

Terman and a few others might take exception to this. And, while I do have
an antenna book in print, it is of the "Little Golden Cookbook Of Antennas"
class. It wasn't that I had the time to write it, the product that goes
along with it demanded it.

That is possible to do, and then integrate the whole shebang. That ain't
exactly an approximating shortcut, and the integral is messy beyond my
capabilities.

>

Uh, no, I want to know R and jx. whether or not it is + or - and which way
it goes. I'm not building tuners. I'm trying to understand the
relationship between the design parameters.

>
> Programs ENFDEED and DIPOLE2, and some of the others, not only calculate

Zin
> but L uH and C pF, antenna loss, feeder loss, tuner loss, ground loss,
etc.

Yessir, and you have done a great service posting these. I could take an educated wild assed guess at the formulas by plotting a large number of data points with these programs, examining the resultant curve, and getting an empirical formula that would match the curves arbitrarily close. My goal was NOT to have an empirical formula, but some sort of foundation on which to believe what my numbers are telling me.

>

No, and I wouldn't ask you to share formulas that you worked out for yourself if you choose not to share them. That's any designer's right. I have absolutely no problem with the results obtained from these programs.

>
> Download ENDFEED, BOTLOAD and DIPOLE2 from website below. Each is one self

And the request (see below) was a pointer to the equations, not formulas hidden inside of programs. Again, thanks for the programs, but I'd like something more than cookbook engineering to work with.

Bill, W7TI wrote:
"You can never get the balance exactly perfect and neither condition is desirable." (Acidic or Alkaline)

There is litmus testing. In alkaline solutions litmus turns blue. In alkaline solutions litmus turns red. Perfection is elusive but close is good enough.

Acid flux is used and has long been successfully used. It`s normally kept away from radio chassis by repairmen to avoid splatter onto fine wires where it may not be removed and may result in the corrosion and failure of these fine wires.

On large antenna wire this is no big problem. I`ve had enduring success with many such applications.

Best regards, Richard Harrison, KB5WZI

I'm afraid that an emperical formula based on curve fitting is about as good as you can do. The real formula is Hallen's integral equation, which can only be calculated numerically. The only (almost) closed form approximation I know of is Shelkunoff's approximation for straight wire dipoles, based on a transmission line analog. It's not extremely accurate, but is plenty good enough for most purposes. The equations have quite a large number of terms which include sine and cosine integrals. I said "(almost) closed form" because the sine and cosine integrals have to be evaluated numerically, or by summing terms of an infinite series until the result is close enough. Although complex, it's not a hard equation to implement on a programmable calculator or computer, but it's nothing you can punch numbers into with a non-programmable calculator. I've written implemenations of it for everything from an HP-41 calculator and PDP-11 through modern PCs, and imagine it's what Reg uses in his programs. You can find Schelkunoff's approximation in "Theory of Antennas of Arbitrary Size and Shape", Proceedings of the I.R.E., September 1941, p. 493-521. It's discussed some in Leeson's _Physical Design of Yagi Antennas_, where it's used to calculate a constant-diameter equivalent for a stepped-diameter wire to get around a problem with NEC-2. EZNEC uses Leeson's method for its "stepped diameter correction", but uses something more like Hallen's equation for actually determining antenna impedance.

Hi Richard,

If I were to mention anything, it would be to add that the last
prototyping shop I worked in used acid core solders typically and
washed the boards faithfully. The reason was that for some reason the
EPA didn't have as much trouble with this method as with any OTHER
flux based system (apparently more ecological damage from them).

Simple dilution. No one worried about neutralizing because it didn't
matter. In any process there is a wash, we went straight to the wash.

But woe to those who went with solder in hand from production to R&D
or vice-versa.

There's the difference between the professional and the amateur. If
you had a single moment's trouble with imbalance, you should have
fired the design engineers, because they had near-ideal conditions in
which to install the antennas and feedlines.

Amateurs don't.

>Ian is too pessimistic.

If the antenna is inches away from the metal you will have problems.
If the antenna is a few feet above the RV, then it should work fine
although there probably will be some coupling which will effect
tuning. If you tweak the legs to have a good match, it should work
fine. But the same antenna inches above an RV will likely be a dud,
and not much better than a conventional vertical mobile antenna. Maybe
worse. As Gary found, I've also found any wires near car metal will
kill an antenna dead in the water. If the wire is capacity loading for
a vertical on the car, and the coil is also near the car, I mean
REALLY dead. :(This can be modeled. "Metal Structures"

Myself, I usually just sling a coax fed dipole over any nearby trees.
I don't worry about other campers. They will get over it. I only worry
about campsite owners complaining.:(I've never had to yank one down
yet. Most see the radio on the picnic table and get curious to what
the heck I'm doing. I've used many that were only 5-10 ft off the
ground that worked great, but they were not near metal. I also have a
drive on mast holder which can hold either rat shack TV mast , or
fence top rail. It will easily support a dipole at 20 ft, and still be
easy for one person to put up. If I don't have trees to tie the ends

off to, I just run leaders to the legs as insulators, and tie them off to ground stakes. I prefer to sling the ends over trees if possible though. If I can't do any of this, I just use my mobile antenna. MK

I don't think I can be any more specific. It's easy to look at a
particular configuration and see what the effect of ground resistance
is. This can be done with even the demo version of EZNEC, by using a
MININEC-type ground and inserting a resistance at the base of each
element to represent the ground loss.

jim: your problem may not be corrosion, but lack of heat instead.

that wire may be acting like a big heat sink, and if your heat source is not large enough, the heat is traveling up the wire, and the end will never got hot enough to melt the solder and let it attach to the wire.

hope this helps.....

Uh, eutectic is not a flux. Eutectic is the particular percentage of
an alloy (tin/lead solder in this case) which has the lowest melting
point and which (at least in the case of 63/37 Pb/Sn solder), when
cooling, transforms from liquid directly to solid without an
intervening crystalline state.

If my memory serves me correctly that antenna was
developed by a University out East, round about the same time
the cross field antenna was published (1992?) I may have made mention
of it on this forum at that time and did discuss it with Mr Hately
personally because on first glance it appeared connected.
From memory it was a toroid around 6 feet in diameter and not very
high (2 feet?
and was also focussed on the broadcast bands I.E. low antenna as is
the
cross field antenna. I seemed to remember that the designers went
private with it, possibly patented it and I heard of it no more but I
have been out of
the ham radio chat loop for some time.
I may come across more info with a picture as I am presently reviewing
my records of the early to middle nineties to refresh my memory on my
work with the multi frequency monoband antenna referred to in another
posting.

Patrick,
As a follow up to my last post I checked my records
and found that when looking for best signal on the S.A.
it coincided with max gain(and sound) but an impedance
that was not totally resistive across the spectrum so I opted
for a tuner. The same antenna could be tuned
from the shack remotely to get unity swr(in the shack)across the
spectrum
from 2 meters down to around 8 or 9 meg hz)
However, by going with best swr (no extra matching)
the forward gain deteriated rapidly where as by tuning for maximum
sound, gains were BETTER than monoband (fixed length elements)
but with deteriation as you say, in the rearward direction.
I migtht add that when I posted this particular antenna on this forum
it
was not received too well by the experts so I moved on to
capacitive coupling of the same elements to each other,as well as 13
element antennas(fishing poles) with TWO REFLECYTORS, again to
receive a drubbing from the resident experts.
Even tho it appears to be a simplistic question it is because my self
confidence has taken a bashing in the past. (Hi Tom)
Best regards

I remember a QST article where a guy tried different versions of 1/2
wave ground mount verticals on 15m?. He started out with parasitic
elements but had problems. The gain didn't really pan out as expected.
He had the best results with them all driven as I remember. I think
Richard Harrison once said he knew the guy that tried them. He may
remember more details. I'd have to dig out the QST to find the
month/year. MK

Dipping in Muriatic acid works well. Just swish it around in clean
water afterwards to remove the acid left behind in the strands.
Muriatic/hydrocloric acid leaves no residue, even the HCL will
evaporate in a few minutes, but for the sake of your tools, etc., it
is best to remove it well before proceeding.

It is quite possible that the comment about insufficient heat is also
important here. It can be surprising how well a large wire can conduct
heat away.

The expensive device they are trying to sell is a capacitor and resistor and a connector available at radio shack. It is a timing circuit that holds the transmitter keyed for about 15-30 seconds with about 10 Watts out.

Do a search on one of the radio mod sites and find the instructions.

This is basically what the auto tuners do, Hold the rig keyed at 10 watts until a low SWR is indicated.

2688. Linear Trap Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-06 07:13:17 UTC
From: David C Dawson <beagle7@pacificcoast.net>
Message-ID: <3C60D7EF.ABEAA1C1@pacificcoast.net>
Source record: 149026

Hi. I would like to hear from someone who has built the linear trap dipole described in the July 1992 issue of 73 Magazine, or some varient of it.

I attempted to make an 80 meter version of this antenna, which meant two more traps, but was unsuccessful due to a poorly operating antenna analyser, the metal on the roof, and the fact that a full-sized 80 meter dipole has to be bent to fit on an 88 foot by 40 foot roof.

IF i try it again, I will either make the 40 meter version and keep the coil-shortened 80 meter antenna I have plus the 30 meter dipole I have. These are parts of a Dynamic electronics multiple dipole I have already.

I wonder if I actually could have made the 80 meter version work by bending it 15 feet or so either end?

Anybody have any experience to relate to me about the linear trap dipole?
Thanks

Source record: 149028

I wanted a relatively unobtrusive vertical antenna for my house, after a lot of scientific research (basically, I asked two people) I settled on the MA5V.

Assembly: piece-o-cake, about 45 minutes with the help of my 3 year old (15 minutes otherwise). The most time consuming assembly is the RF choke at the bottom, a length of RG58 wound on a PVC form.

Finished product: it's light, under 8 pounds I believe. Feels solid enough though. It's rated for winds up to 80 mph according to the spec sheet.

Operating: I don't have anything else with which to compare it side by side at this location. Suffice it to say I can copy a lot of stuff with an ancient Drake RX4C I am in the middle of restoring.

Value for the money: I always wonder why we pay so much for a few pieces of aluminum and stainless steel, but I guess it's all pre-cut, pre-drilled and, in some cases, pre-assembled. $199 at HRO in Sunnyvale, CA as I write this. I can't complain too much about the price I guess, it seems to get the job done. I would buy it again.

The instruction manual says something about a 6m resonator, but I don't see one listed for sale anywhere. Maybe it hasn't been released yet. Does anyone know if such an animal exist?

Hi

I have heard that the size of the cable matters. I do know that if the shorter then its better, but i do also heard that its size must be the multipler of the lenght of the radio wave for the best results. So do you know what size of the cable i should use?

Greetings

Source record: 149033

I was wondering if there was a web site with information as to the formulas, specifics etc. about using steel, copper, aluminum and other metals for construction of amateur antennas.

Questions I want to learn the answers to are:

Diameter and wall thickness of tubular material, how does it affect performance?

Specific Material performance, i.e. copper vs. steel and so on.

Can solid core work or must it be tubular?

What methods of protecting the metal used do not affect performance? (paint? laquer? clear coat? etc)

Thanks in advance! I am going to be building some antennas soon, and would like to learn about those questions posed.

For those who may not be well versed in antenna theory....

Gain and directivity are directly related only if there are no losses
in the antennna.

If there are losses then the gain will be less but you will have the
same antenna pattern. However, with a parasitic array, the losses may
affect the mutually induced currents which will affect the pattern.
Everything would have to be carefully adjusted.

Using a circular array of driven elements is a simplifying 'trick'
because all the elements have the same mutual impedance and it can
then be essentially ignored.

Sound ok, Roy?

Faced with a similar situation in a Maryland "townhouse" development I told the worst gossips in the hood that I was going to move. "Yasee", "I explained, the county welfare people made me an offer. My place already has 3 br's and 2 1/2 baths. They can add 2 more BR and rent it to an indigent family with up to eight kids; collecting whatever the family can afford but paying me market value: enough to cover my mortgage, allow me to keep the house as an investment, but live where I can have my radio antennas." The prospect of having an 8-kid welfare family in their oh so nice hood so appalled them that I got put on the list of people to be nice to!

The type of inductor winding that you're talking about is also
known as "regressive". It achieves higher Q by way of reducing the amount
of leakage inductance. If you look at my technical bibliography on
inductors on my web page at:

www.primenet.com/~ctrask

you'll find at least one article on regressive windings. If not, let me
know and I'll see if I can dig it up. I know it's around here somewhere.

Mark Keith wrote:
>
> If the antenna is inches away from the metal you will have problems....

Thanks Mark, but AFAIK there is little/no metal comprising my particular RV. The walls and roof are a strong self-supporting composite of foam inside hard f'glass sides, about 2" thick. There are a couple wires in the roof feeding lighting and an AC unit. Seems to me that a dipole strung above it low enough to clear overpasses, etc, would act much like a dipole up 12 -13' over metal rails representing the MH frame, motor, etc but, not having tried it yet I dunno.
> >
>
> Myself, I usually just sling a coax fed dipole over any nearby trees.
> ... I've never had to yank one down yet. .....

That's been my experience too. A friend bought a collapsable f'glass flagpole with a drive-on base from Camping World - uses it to support a dipole or runs a wire up the side as a vertical to be less obtrusive. Even the latter gives him a full 1/4 wave on 20m, which otta perform better than a shorter coil-loaded antenna.

The screwdrivers I've seen are compromises designed to fit cars. That's fine but I'd like to use the size of my MH to minimize those compromises. One step might be a screwdriver or bugcatcher with a 16+' inverted L in place of the more typical 9' whip. Beyond that ... ???

Ryan,
Do a search for antennas and vary the type of antenna
as a search parameter, ought to find more than you'll ever
want to know.
The conductivity of different metals has little to do
with the average antenna, one works about as well as another.
The diameter, wall thickness etc, has more to do with strength
than anything. Pick materials for strength and lowest weight.
Protecting the tubing from the weather depends a lot on the
type of tubing used. With aluminum, I wouldn't worry about it
too much. If you use some other metal, it won't be the weather
that causes a problem, but weight sure will. The solid vs.
tubular thing has more to do with weight also, either will
work fine for most antennas.

fachman,
The important thing is the loss in the feedline, not
it's size. For UHF/SHF the size will probably be larger
than for HF, but that has to do with loss of the cable.
If you're speaking about using a wave guide for a feed
line the 'size' does make a difference, but I really
doubt if that's going to be a problem for you...
'Doc

If you are going to invest money in a tower and an antenna and the spend the time to put it up, talk to a lawyer first. No judge is going to care very much about basketball hoops, satellite dishes, and cars parked on the street, if you have to go into court and say that you knowingly violated your CC&R, just because you saw everybody else was and nobody was doing anything about it. Especially once you are in court because someone complains about you.

Talk to a lawyer, this is not a situation like the misquoted remark about jumping off bridges, the is more like the old oil filter advertisement : you can pay a lawyer a few bucks now, or you can pay your lawyer, their lawyer and the court fees later, plus whatever penalties are applicable after you take down the antenna.

On the home front, after you talk to a lawyer, talk to your neighbours before you do anything. The laws here in Canada are a little different (thank God) but the Radio Amateurs of Canada (RAC) still advises that we follow a set procedure that includes notifying any neighbour who will be "visually impacted" by the "antenna support structure" (read tower). There is no legal requirement that we have to get their approval, we just have to notify them in a timely fashion (i.e. more than an hour before we put up a 300 foot tower with a 10 element 80 meter Yagi).

Talk to the lawyer, it will cost you a few dollars now, but so does auto insurance, it just means you might not have to pay as much later or end up investing in equipment that you can't use. If you want to visit a few web sites and get some info, go for it, print out what you see, with the URL and find out what state it refers to and take it with you to the lawyer, but talking to a lawyer beforehand is always gonna be cheaper than afterwards.

Sylvan Butler wrote:
"I suppose that before I bond to the existing rod I can check for
galvanic potential between new electrodes and old ground system."

PIcon, a Canadian cathodic protection (CP) company says buried piplines
are protected by:
-850mV vs Cu/CuSO4 in conjunction with polymeric coatings. The voltage
is measured between a pipeline and a copper sulfate electrode to earth
such as those made by the M.C. Miller Company. Test leads are attached
to pipelines at appropriate locations.

A typical impressed current system puts the negative rectifier output on
the protected structure (pipe) and the positive rectifier output on an
inert anode (graphite ground bed).

The impressed current flowing through the soil into the pipe overcomes
corrosion current normally flowing away from a (steel) structure.
Choose your own current convention to make this work out.

Best regards, Richard Harrison, KB5WZI

Thanks, Roy. I was afraid that I was missing some "aha" factor when I saw the equations. I figured that the COULDN'T be as messy as they were, but you confirmed that they are just as messy as I thought.

The real answer seems to be take some curves you believe and fit an equation to them. That's the sense of what I'm hearing.

Hi Dave,

You are worried about the wrong thing. Today's headlines (literally)
about microsoft reveal how their instant messenger service and outlook
express will expose your list of buddies and their e-mail addresses.
And this on the heels of news about their "Passport" exposure
problems. New headlines come out about once a week.

Just one more of those special features they design before they decide
if you need it, much less can trust it. Their solution, by the way,
cripples IE6 - but then with their commitment to security that is
probably a blessing in disquise.

Correlation may not be causation, but it is startling with the
coincidence in the rising popularity (?) of IE and the explosion in
identity theft. Given the already proven causation, it seems a
strange argument that downloading your credit history to hackers is a
suitable cost for a faster loading browser (an often inaccurate
claim).

There is nothing on the net that has changed the news nor e-mail
protocols in a verrrrry long time. Agent, the commercial form of
FreeAgent, has been my software client for these services for 5 years.
At no time has it ever been nicked by viruses - much less crippled or
responsible for passing on the infections like MS products.

2720. Re: The size of the cable for 2,4GHz Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-06 18:19:24 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3c618603_2@news1.prserv.net>
Source record: 149061

Here is some general information on coaxial cable at 2.4 GHz. The first column in the table is loss in dB per 100 feet. Then, since I suspect that won't mean much, a second column which is feet for 3 dB loss. 3dB is half of your power, and a usual rule of thumb for maximum transmission line loss. Note that only one RG number is given, but at this frequency, the loss is directly related to the diameter, and any cable with the same diameter will have very nearly the same loss.

Cable dB/100' feet/3dB
RG174 64 5'
RG214orRG8 19 16'
RG17 9 33'
3/8" LDF Heliax 6.6 48'
1/2" LDF 4.4 68'
7/8" LDF 2.5 118'
Teflon
RG188 58 5'
RG142 26 12'
RG87 14 21'

So, if you intend to place the antenna very far from the equipment, be prepared to use some big coax, or loose any advantage of an external antenna.

Don't overlook the fact that you aren't locked into using ONLY a mobile whip with the screwdriver
base - you MIGHT see a substantial benefit from attaching the base to a substantially longer run of
wire, and then use the screwdriver base to "tune" that random wire. I have used that method a number
of times - and it works great, especially on he lower frequency bands - 40 meters and lower...

Message-ID: <Dhf88.1747$Re7.51844@typhoon.austin.rr.com>
Source record: 149060

Is there a site which generates azimuthal maps similar to

http://www.wm7d.net

but the map is a more recognizable projection of a specific area? In other words if I generate an azimuthal map centered on Texas, the US and South America look pretty good, Africa is barely recognizable, and Europe and Asia do not resemble Europe and Asia at all. I would like to see a map of Europe or Asia (only) showing the projection lines coming from Texas. I realize that the lines would no longer be straight, they would probably be portions of a sine wave, but I would be able to identify countries within Europe.

All information will be greatly appreciated. Thank you.

Hi all!

I was helping a buddy of mine get his DX-77 antenna together, plus hole dug and mast cemented into the ground when we came upon the description of how the tilt-over section is suppose to be assembled. Since the picture is in 2 dimension, it is very hard to get an exact idea of how this is suppose to be mounted. If anybody has assembled this antenna and have photos of how the tilt-over section was assembled, please send them to me via my e-mail address.

Source record: 149064

Hi Bill,

I have a 99 Ford Ranger 4x4. It is an excellent truck but a miserable RFI source on HF. I have the fuel pump added filter in the tank. I need to put some straps between the bed and cab.

Having said that, I have never had any noise problem on VHF. My 2 meter radio works well in the fringe areas of the repeaters.

There are rubber plugged holes in the bottom of the cab below the seats, that are relatively easy to get to. I put an antenna hole for the VHF 5/8 in the top near the dome light. It is sealed with the standard O ring sealed through hole mount. The Coax is snaked behind the liner to to floor. I live in a very humid and wet environment and have had no leaks. when I sell the truck, I will either install a plug in the roof or a small business band whip.

I like the 5/8 much better than a 1/4 for 2 meter use. Coverage is much better. I also have a Larsen dual bander that is a little shorter than the standard 5/8 that works very well.

I have had good luck with mag mounts but use caution to avoid scratches and dirt around the edges. Lift it off, do not tilt it off. Extra coats of heavy duty wax on the truck may help. I have used a thin layer of teflon tape on the bottom of the mount with success to help prevent scratches to the paint. I usually run the coax over to the passenger door and route it under the door seal to the floor level. Use some sort of drip loop at the top to prevent water running along the coax to the inside of the truck. I have used Duct tape to secure the coax inside the door opening. The silver stuff deteriorates in a year or so and makes a mess. If you can get the real stuff (Green, Mil. grade) use it.

For the record, my large HF whip is installed on a custom SS bracket that bolts onto the rear of the truck under the rear fold down gate latch at the top of the bed. It is basically an SS plate with enough of a Z bend in it to move the bolt heads away from the the door as it opens. The plate protrudes out between the Gate and the bed within the clearance for the door to close. The latch bolts are used and no extra holes are required.

I like my truck but I think the next one will be a Dodge Diesel because of the Ford HF noise problems.

Aloha,

John KH7T

Not really. Compare LMR-400 with the RG8. Times Microwave rates
it at 2.5ghz:

LMR-400 6.8 44'

> Cable dB/100' feet/3dB
> RG214orRG8 19 16'
> RG17 9 33'
> 3/8" LDF Heliax 6.6 48'

Obviously it performs more similarly to 3/8 heliax but is size-wise
a drop-in for RG8. Also available in an "ultra-flex" (stranded
center, etc) at 15% worse attenuation. Also available as
direct-bury, plenum, etc.

> So, if you intend to place the antenna very far from the equipment, be
> prepared to use some big coax, or loose any advantage of an external

I reduced AC power line buzz that was being radiating from a defective Pole Transformer by using the MFJ-1026. The trick is to be able to place a SENSE antenna where it picks up mostly only the noise. Phasing out the buzz resulted in a reduction from S9+10 to about S4. After about a year the Pole Transformer finally went up in flames. I now use the 1026 sense antenna input to couple in a 350 ft low Beverage RX antenna.

Jim says -

> The real answer seems to be take some curves you believe and fit an
equation to them. That's the sense of what I'm hearing.
==========
Jim, ;o) get yourself a hearing aid, you are are hearing wrong !

I have never read the tomes nor have I even heard of most of the many
authors of the books and papers mentioned in this waffling overcomplicated
thread. I don't doubt that most of their conclusions are published in the
form of 'curves'. But curves, inevitably, can apply only to restricted
ranges of parameters and are poor sources of information on which to base a
practical understanding of what's really going on.

Terman (who I *have* heard of and have 1937 and 1943 wartime editions of his
books) relies on curves. But I have never found any of his curves to be of
any practical use. (But then, I have never used a Smith Chart either).
People who quote, recommend, even worship him have no doubt familarised
themselves with his writings but have seldom tried to make much *practical*
use of them otherwise they would not have set him up on a pedestal.

To fend off assault I hasten to add that many years ago I discovered
Terman's indeed comprehensive writings (and some of his curves) were of
considerable educational value and a valuable set of reminders. A
check-list. A safeguard against omitting essentials. But for getting down
to basics, Everitt and his ilk were a superior little bunch.

If you are more than just another author yourself, when trying to solve a
particular engineering problem you must have been many times disappointed to
find most sets of recommended curves fizzle out at the edges of the regions
you are really interested in. To try to base a practical computer program or
another practical book on sets of curves preconceived by other gurus is a
waste of time. The important thing is to recognise and appreciate a waste of
time before getting bogged down in it.

It may be of interest that NONE of my programs (as imagined by Roy) are
based on number-crunching curve fitting. So far as I can recall numerical
integration (Simpson's) is used only to predict radiation resistance. The
great majority of calculations are done using explicit algebraic expressions
deduced by fundamental engineering reasoning which any competent electrical
engineer should be able to do for himself.

When I first discovered the internet and websites, and began giving programs
away just a few years back, I was very surprised to discover they, or
similar, hadn't already been produced 10 or more years before. Nothing was

copied. There was nothing to copy from. I undertook the work as a hobby to find something satisfying to do in retirement.

And, as I have said before, the principal reason for witholding program source code is to allay unfounded, ill-educated criticism by sincere do-gooders, nit-picking trolls and cantankerous 'old wives'. Unfortunately, mud sticks and confidence can be undermined.

Here comes the flack ! (A ww2 understatement.)

Al:
The answer is sort of. Some guy at Datapoint had such software, and we had
a copy of a large map printed from it where countries could be recognized,
but it was given away.

2739. Re: 7 element electrically steerable vertical phased array

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-07 00:47:50 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C61CEB6.C58F5470@eznec.com>
Source record: 149077

Unfortunately it's not quite that simple. Those who have EZNEC (even the demo) can follow along with a simple illustration. Open NBSYagi.EZ and delete wire 3, the director, to make a simple two element Yagi with driven element (wire 2) and reflector (wire 1). Run a far field plot and note the gain and front/back ratio. Add a 100 ohm resistive load at the center of wire 2, the driven element. (EZNEC will put it in series with the source.) Note that the gain has decreased, but the pattern and front/back ratio are the same as before. Increase the resistance to 1000 ohms. The gain is down more yet, but the pattern and front/back ratio are still unchanged.

Now put a 100 ohm resistor at the center of the parasitic element, wire 1. What happens to the pattern and front/back ratio? (For those who aren't trying the experiment, the answer is that the pattern looks like a slightly lopsided dipole, and the front/back ratio has decreased.) The more resistance you put at the center of the reflector, the more the pattern looks like a plain dipole. And there's no amount of resistance you can add to the driven element to restore the original pattern.

On the other hand, you can insert resistances of any values at the any or all the bases of cardiod model Cardioid.EZ or four square model 4Square.EZ without changing the pattern shape, regardless of the amount of resistance you add and which elements you add them to. The reason is that the model antennas are driven by current sources, so adding a serie resistances at the bases doesn't change the relative amount of current going into the elements, or the current distribution on the elements.

So loss can be added without changing the pattern only if it's added in such a way as to reduce the current in every part of the antenna in the same proportion. But it's possible to add loss in ways that don't satisfy this requirement.

As far as ignoring losses goes, the effect of loss has a lot more to do with coupled impedance than mutual impedance. The mutual impedance depends only on element length and orientation. It's the same for two parallel elements which are both driven as for two parallel elements of which one is parasitic and the other driven -- or for two elements just sitting there. Yet as you've seen, the effect of loss is much greater on the parasitic element. The coupled impedance depends not only on the mutual impedance, but also on the relative magnitudes and phases of current in the elements. In the case of a parasitic element, the coupled impedance equals the negative of the self impedance, resulting in a zero feedpoint impedance. Any loss in series with this has quite a profound effect.

Richard Clark wrote:
"The reason was that for some reason the EPA didn`t have as much trouble with this method (acid flux in production soldering) as with any other flux based system (apparently more ecological damage from them)."

EPA probably has a point. The composition of acid flux is probably a very short list of well understood chemicals. Good clean acid should be no problem if diluted very well and it`s been around forever. Who knows what might be used in other fluxes?

EPA is a force to be reckoned with everywhere, and with some cause. Cathodic protection used to be just good business. It was an operating and maintenance expense, but the best bargain available. Now EPA mandates cathodic protection of buried tanks and pressure piping which contain regulated substances. Too many gasoline station tanks leaked into the environment.

Likewise, oil, gas, and chemical pipelines were just about all protected cathodically before regulation mandated the practice. The DOT mandate for high pressure testing is more controversial. The practice seems to trigger subsequent failures. Sooner, if significant yielding results from testing. Later, if slight yielding produces tiny stress cracks in the steel which operational pressurization cycles enlarge into something serious. Examinations of blow outs have seemed to link them to the high pressure tests. The lines normally operate below the test pressure, so the test is really an overstress.

Never mind, EPA is here to stay, even if it hair-lips every cow in Texas.

Best regards, Richard Harrison, KB5WZI

That is only the case if you have just the six outer elements (no center
element)
and you drive them with the same current (a fairly useless configuration).

In the case of my 7-hex array, since the currents are different, the mutual
impedance is a big player. My phasing network forces the currents in
spite of the coupling. You can model the coupling and the drive impedances
of the elements on EZNEC if you want, but they don't really matter because
of the forcing arrangement.

Wrong buffalo breath! I'm the 2nd term Pres of an HOA and we do select which rules to enforce and when. It's written into the charter and Design Standards that since every situation is different, lack of enforcement of a rule in one situation doesn't mean we can't enforce it in other situations.

You signed a contract. If you didn't read the CC&Rs before you bought the property, that's your bad. Be a man and live up to the obligations you signed up to. Other people probably moved into the neighborhood specifically because there were CC&Rs - don't violate their rights because you're some sorta "I'm gonna fight it..." macho man.

If you go to court, guess where the HOA's legal costs are paid from? Your dues!!! You lose either way dufus!

Modifications for the Icom IC-706

Picture(s) of Icom - IC-706
Here is the TUNE PLUG MOD

IC-706 10 watt tune modification/An Icom IC706 Tune Trigger

Author: Larry Lefczik, WA2EHZ - WA2EHZ@juno.com.MODIFICATION.NET

(Some assembly required)

The ICOM IC-706 has a nifty feature built in to help the operator tune the HF antenna SWR. By pushing the TUNE button on the front panel, the radio switches to CW mode and transmits a 10 Watt carrier. This state last for approximately 10 seconds or the operator can terminate sooner by pushing the button again. This was designed to work with the Icom automatic antenna tuners. There have been a few circuits developed to fool the 706 into thinking there is a Icom tuner attached and produce the same tuning signal which can be used with a manual antenna tuner or many automatic tuners, some get quite complex.

Well, being the cheap guy I am, and being one to tinker, I felt there had to be a simple way to do this. I began reading the various postings on
the Internet. I went back to an e-mail exchange I had with Ed, W1AAZ in early April 1999 on Vartel's ICOM 706 Discussion Group. Ed explained the functions of the TKEY and TSTR pins on the "AH-3" connector on the 706.

The outcome was a simple RC circuit which I have built right on a Molex connector which plugs into the AH-3 jack on the back of the IC706.

CONSTRUCTION:
The (+) side of C is connected to the 13.8VDC pin. The (-) side connected to TSTR and TKEY which are connected together. Resistor R is in parallel with C. Below is a diagram of the AH4 connector on the back of the IC706 where the < indicates the pointy end of the connector (Pin 1 = TKEY). You can buy the Molex connector at Radio Shack (#274-0224).

```
< TKEY TSTR 13.8V GND ]
|_____| |
| R |
+--///--+
| + |
+----)(----+
```

C

The values I use are C=1000uF 16WV R=92K Ohms 1/8 Watt which result in 15 seconds of tune time. As you can see, these are tied in parallel. If you want to use a physically smaller capacitor such as 440 uF, you can adjust the time by raising R. The extreme values I found are:

2K

OPERATION:
Be sure to read the manual about the various Initial Settings that can affect the operation with a tuner connected, otherwise you may go
into the TUNE mode every time you change frequency or push the PTT.

Turn off the radio and plug in the unit. Make sure you have some sort of load on the HF antenna connector. Turn on the IC706, the radio sees TSTR is high during boot up and thinks there is a tuner connected. Be sure the meter is in the SWR mode. Push the TUNE button. The TUNE light should flash counting the seconds and stay lit when finished, as stated in the manual. You may interrupt the cycle by pressing TUNE again.

If you terminate the TUNE mode early by pressing the button again, you must wait for the remainder of the time-out period to re-start.
If you don't then the cycle is started over again when you press TUNE and you still must wait, but longer. This is why I have opted for 15 seconds instead of a possible 30 seconds. One way to reset the timer is by powering the IC706 off then on.

I have noticed false triggering when the supply voltage AT THE IC706 POWER CONNECTOR drops during transmit and C has not yet totally discharged. This is caused by the TKEY voltage dropping through the trigger point because the supply voltage drops while
C is discharging. This lead me to upgrade my power supply cable so there is less voltage drop when I transmit.

ALTERNATE DESIGN:
You can eliminate the capacitor and the TKEY to TSTR connection if you want to manually trigger the IC706 into TUNE. You do need the pull-up resistor between TSTR and 13VDC to make the radio think there is a tuner present during power up. Then ground TKEY to trigger the TUNE mode as long as TKEY remains grounded.

Thanks to Ed, W1AAZ for the explanation of the connector.
Enjoy!

Forget about using a torch. It will burn off your flux leaving a mess. Use an large iron. Scrape or use fine 300-400 grit to clean to bright copper. You may have trouble with some steel if you go too deep into Copperweld though.

With 'curves' include 'tables'.

Curves can be fitted to. Tables can be interpolated within.

But algebraic expressions take precedence.
C and T follow later if needed.

It is cheating to work backwards in order to write books.

Well, publishing curves and tables but not the equations from which they
were derived might be said to be the analogue equivalent of not
publishing the source code. This is not to say that your reasons for
withholding source code are not justified.

I expect that it depends on the particular HOA agreement, and even the
state in which you live. The few agreements I have read do not have the
wiggle clauses that you mention - although I can see some slimey association
putting them in so that they can do as they wish.

2756. Re: Antenna Construction Materials

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-07 08:41:31 UTC
From: ok1sip@atlas.cz
Message-ID: <8f3e93b5.0202070041.19a1f71d@posting.google.com>
Source record: 149092

Hi Ryan,
IMHO:
> Diameter and wall thickness of tubular material, how does it affect
> performance?
Keep in mind, that RF currents flow in a very thin layer near the
surface (tens of microns). Only this layer affects electrical
parameters of the antenna. The greater the outer diamater, the bigger
the surface is and the lower is the loss resistance. Simultaneously,
the bandwidth of the antenna increases. The wall thickness must be
considered for mechanical purposes only and has no influence on
electrical parameters.

> Specific Material performance, i.e. copper vs. steel and so on.
Copper is quite strong, conductive and can be soldered easily. It is
almost perfect for wire and small experimental antennas. It is a bit
costly and heavy for beams, Yagis etc.
Brass works nearly as well as copper, is cheaper and even more strong,
but oftend breaks when frost.
"Hard aluminum" (Al alloy) is fairly conductive, strong, lightweight
and cheap. The main disadvantage is it cannot be soldered in a
standard way. It is the favourite material for antennas made from
tubing an/or bars. Pure aluminum is too soft, otherwise it has the
same properties.
Steel is good for towers, but I would not use it for active elements.
It is quite lossy and ferromagnetic. Good corrosion protection is a
must.
On the contrary, copper plated steel (if available, e.g. from military
surplus) is very good. The copper surface is very conductive, can be
soldered and protects the steel core from corrosion. The steel core is
strong and does not affect electical parameters (see higher).
Another, more exotic materials ? Ask !

> Can solid core work or must it be tubular?
See higher: only the thin surface layer works. So electrically a pipe
and a bar of the same outer diameter, length and material are
identical. Consider mechanical properties.

> What methods of protecting the metal used do not affect performance? (paint?
> laquer? clear coat? etc)
Most paints do not absorb RF too much up to some GHz, but it must be
tried. Copper and aluminum alloys usually do not need any protective
coating.

Sure, that works great and increases the efficiency quite a bit. The only thing is to run the wire off away from the car or rv to a tree or small mast. I once talked to a friend of mine who was down on the coast towards Corpus. He had only a 40m hustler antenna, but it was getting dark, and 80m was the better band for us. He was about ready to hang it up, but I just told him to clip a wire onto the top of his stinger and run it off to a tree, which he did. Worked fine. I'm sure better than most normal 80m mobile antennas being so long. As mentioned, it's also a handy way to change bands with high band hamsticks, hustlers, or whatever. You can take a 10m hamstick on the car, and some wire and clips and work all bands as long as you are sitting still next to a tree. And the efficiency will be fairly high on all bands. You might need a pretty long wire on 80m though... Once you trim a wire for a band, keep it for future use so you don't have to keep trimming them. I do the same thing with stinger whips in order to be drivable. My normal 20m antenna is 5 ft of stick, with 2 ft of stinger. It works much better on 20m than the 20m hamstick I have which is pretty lousy with it very short stinger. I use the 20m hamstick and a 5 ft stinger for 40m. But I once tried this same thing, only running the wire across the roof and sloping downwards and tied off to the front of the hood. Was terrible. I could hardly get out at all although it would seem to be working ok at first glance. I took the wire off, and gave a quick call and I was back to normal. The coupling to the roof and hood just killed it dead. MK

Hi,

I've done the following in the Past,
Use it to feed a dipole cut for the lowest frequency of interest , fed with
open wire or Ladder line. contenting one side to ground and the other to
end fed wire will work if the wire is approximatel 1/2 wave or odd multiple,
if wire is 1/4 wave or odd multiple by pass the balun. End fed 1/2 wave fed
with 1/4 wave open wire connect balun to open wire line.
Hope this will be of some help.

Thanks. I might have to make me one of those. I knew they existed, but I had never bothered finding a circuit. It get's kind of old having to switch to AM or RTTY and then reduce power in the menu to check SWR. I wish they would have used a tad more power than ten watts though. The SWR metering doesn't seem to be too accurate until you are doing 20-30 watts. "Comparing my 706 swr meter to my outboard meter". But I guess it's still plenty for finding the dip when tuning mobile. MK

>

Yes, I forgot to mention 'no center element'.

The current magnitude would be the same for a symmetrical, but the
phases can be different. Since all the feedpoint impedances would be
the same it makes it easier adjusting the phases.

However, in the most general case you want to be able to adjust both
the phase and amplitude of the current. There are ways to decrease
the sidelobes, at the expense of a slightly larger main lobe, by
carefully tapering the element currents. All of this is explained in
Antennas (Kraus) for linear arrays but can be expanded for 2-D (and
even 3-D) arrays.

It is when you have a non symmetric array, where each element will
have a different feedpoint impedance, that things get fun. I went
through the calculations (brute force, not using Eznec) many years ago
for my MSEE thesis.

No, I am not overthinking it, and was asking a simple question. Every diagram and material I have seen shows it using copper for the elements part of the antenna and the bottom support.

As far as the ARRL materials, there is nowhere to buy them around here, with the closest place being over 2 hours away. I would love to purchase amateur radio texts, but there is nowhere to go and purchase these items.

Thanks anyways...

BTW, that isn't *necessarily true*. I know of at least one case where the court ruled that other homeowners would have to demo that their property values were hurt before a CC&R could be enforced based on previous decisions on racial CC&Rs. They couldn't so the CBr got to keep his antenna. End of story? Nope! As a HOA member he then sued the HOA prez who'd taken him to court in the first place and that *individual* had to repay the HOAs legal expenses for bringing a frivilous lawsuit. He had to sell his house to do so. Naturally YMMV.
Enjoy

AFAIK the "antenna" is just the "J" ... it doesnt matter what the support is made of so long as it is strong enough to support the rest of your creation. I have seen J-Poles mounted on the rear deck of automobiles.

A quick <www.dogpile.com> search for "copper cactus" turned up this among many others: <http://www.n7qvc.com/copper.html> . It's made from household copper pipe E fittings available anywhere homes are built. Alternately, Arrow antenna <http://hometown.aol.com/Arrow146/index.html> makes good looking aluminum J-poles and Yagis out of arrow shafts as the name implies.

The protection circuitry in the IC-706 works to reduce output power
to keep the reflected power limited to a certain amount. For years,
I have found a clear frequency and tuned my screwdriver without
manually lowering my output power setting.

Your portrayal of what non-CC&R living is like is utterly brainless,
bigoted bullshit.

No, what I object to is some nitwit telling me I can't install a split
rail fence around some portion of my yard. I object to the inspectors
telling me after the fact that the color I painted my front door or
the knocker I installed on it are not allowed. I object to a
committee member saying my neighbor can't install a floodlight the
drive way when the only provision in the HOA rules against this is
committee discretion and we both agreed to it.

I don't have a car on blocks in my yard. My kids are well behaved. I
keep my gutters in good repair, and we spend many a day during the
spring, summer and early fall mowing, weeding, planting, painting and
so on.

And guess what? I don't have a CC&R. All I have that might offend
your sensibilities are the occasional company work truck (large
pick-up truck) and a few very discreet wire antennas. Gee. Imagine
that.

You have been living in isolation for too long. Go out in the real
world and get a reality check. Rural living in a 100 year old farm
house ain't what you think it is. You may be living in the veneer of
a bucolic suburban enclave, but if you scratch the surface, I think
you'll find that your attitudes are probably more bigoted and nasty
than any you'll find out here.

Cam,

Take a look at the DX4WIN logging program (even the demo will do this much...). If you enter a call sign (or just the prefix) the program calculates the distance to center of country/state and the correct azimuth from your QTH. If you enter in IOTA number or the grid locator square, the system calculates the distance/direction to that location rather than the center of the country.

When you display the globe (in the QSO details window, select indow, orld map) it draws short and long path lines on a globe depicting the countries of the world. You can zoom in/out by pressing or , and you can set the program to display the gray line boundaries based on time of day. You can spin the globe around by selecting a portion of the world, pressing and holding-down the left mouse button, and moving the mouse. Oh, and you can print it if you want.

Very slick...

In the near future I plan on putting a base antenna on a 10 foot mast and then mounting the whole thing atop of a corrugated iron roof of a house. The whole roof is made from corrugated iron, and the roof is well earthed to the ground on one side about 20 feet from where the antenna will be mounted, by 8 square iron 2" X 2" support posts wich hold up the verandah edge.

I am concerened because I do not know the effects of a potential lightning strike to the antenna, with reguards house damage.
Is there someone who can estimate the likelyhood of damage to the house for me, and what would be the best way to minimise potential damage?

I presume, if lightning hit the antenna, it would be destroyed, and my radio would be destroyed, is there a way to avoid this.

PS, I do live in an area where there are heaps of electrical storms during the summer months

Any help would be apreiciated.

Andy

hey andy
about the best way to avoid the lightening from hitting your rig is to unhook the coax and short it to ground
but there is very little to keep the stuff from hitting your antenna if its a fiberglass one it will rain down all over your yard.....grin
good luck

Jim Bolinger wrote:
"If there are losses then the gain would be less but you will have the same antenna pattern."

Maybe not in both planes. See Fig 3 on page 3-5 of the 19th edition of the ARRL Antenna Book where: "The solid line is the pattern for perfect earth. The shaded pattern shows how the response is modified over average earth---." (Both amplitude and pattern shape are changed by the loss.)

Jim also wrote: "Gain and directivity are directly related only if there are no losses in the antenna."

Sort of, maybe. See above. But, directivity comes from concentration of a given energy into a smaller directional area, and this is identical with gain for a given loss.

Best regards, Richard Harrison, KB5WZI

A number of years ago I picked up a triband antenna. It was a made by a 2 call area ham and sold a a semi commerical short production run antenna.

Its a tri-band (10,15,20). The booms and elements are all fiberglass with imbeded copper wire inbetween the fiberglass to make up the antenna. Its reasonably light want and I wanted to start using it as a portable antenna.

I dont have any assembly or tuning info.

Anyknow have or know more about this antenna. I can provide digital pics if you need additional help

I did exactly the opposite. I started at a place where the HOA ruled
with an iron fist. The last straw was when some clipboard toting
woman with an attitude asked my wife if the color on our door was
approved. My wife replied "Well, it's the best I could do to match a
faded color at the hardware store under fluorescent lights." After
that we wanted out.

Oh and if you think an HOA keeps the value up, get this: I SOLD AT A
SUBSTANTIAL LOSS. That's how bad I wanted out. My only consolation
for losing money on that deal is that it pissed off the HOA almost as
much as it did me.

>This knife cuts both ways. I got pissed when the HOA guys told me I
>couldn't have a hose reel mounted to the side of my house. Well, I didn't
>just get mad - I got even - I'm now the (second term) President of the HOA.
>So, quit bitching and do something!!!

I did it. Now I don't have to do anything about this sort of
foolishness ever again. --That is until the HOA nazis get tired of
their own little enclaves and try to take over the whole county. That
nearly happened a couple years ago.

Enforcing rules of aesthetics on your neighbor seems like an exercise
in mind control to me. I despise it. I don't want to have to run for
office to get my neighbor off my case. If that's what makes your day
complete, more power to you. I'd rather spend my spare time flying my
airplane, tinkering in my radio shack, flying kites in our hay field
with my kids, or dreaming up new tree-house designs. That's my life.
Where's yours? --Oh I forgot: You need to check up on your neighbors,
don't you? Well, I hope you like it.

There are no guarantees, but in similar fashion, airliners fly around
this stuff all the time and even take direct hits, mostly without major
problems. The reason is that lightning is an RF issue! It travels over
the SURFACE of the conductor. Yes, they take special precautions to
keep the stuff out of fuel tanks and helping it leave the airframe! And
yes, there are horror stories. but our Beech Baron was hit a number of
times with me flying it. I'm still here. People on the INSIDE of a
metal cage are generally relatively safe!

If your antenna is a grounded antenna and bonded directly to the metal
roof, and the feed line goes through the roof such that a metal skin
path is created between it and the roof, things should start looking up
for you! At that point, the idea is to make sure that whatever
lightning strike RF voltage that is on the INSIDE of the feed line
conductor doesn't go inside, but is shifted to the outside skin of the
whole system as well.

To that effect, one would presume that you are going to use a coaxial
form of feed line for this antenna. If you then put a proper Polyphaser
or other gas discharge lightning suppressor unit there where the feed

line goes through the roof or, at the point where it exits the roof to go down under it and inside, you may have done enough to stop your worries.

The idea is that you want the inductance along the skin and outer conductor path to be far less in impedance to what will be seen going into the shack. From there the gas discharge operation shunts the surge to that low impedance path for the surge to ground. Inside, your equipment will be relatively safe.

A pretty fair showing of faith toward that statement would be that you have likely never had any damage problems with the roof there that way for anything inside the building, right?

As you investigate this idea, also keep in mind that your real intent is to keep the impedance of the path to ground as low as possible. With that in mind, even though the whole structure is metal, as you say, it is worth investigation to help this out a bit. Where you do the mitigation work to implement this, adding a copper sheet conductor for the ground path down to the ground on the pole leg and shortest path from the gas discharge device, will give you some added protection, per the professional books on all this.

Polyphaser has or had a web site devoted to the science of protection things which must remain working. It's not cheap stuff, and there are other competitive devices. But with the full metal jacket around you to start with, you are starting off much better than most folks to handle the visits!

--> Sleep well; OS/2's still awake! ;)

Our Punchinello a plagiarist?

I love the way this board mimics the headlines of the local paper. We
have a die-hard petitioner (one Tim Eyman) who has claimed for years
he doesn't make a nickel off the initiatives he heads. Not even that
quarter million bucks... for car expenses and stamps. We certainly
live in the age of denial.

But in all honesty, I have never seen Terman reference the measurement
of mud in the kitchen sink, so I think that "Intellectual Property"
may be original to our Old Wife. Is there an uh-zipped MUDPRECISION
program? Woops! The Old Wife sweeps her recipes under her apron as
we approach. ;-)

That last is so funny given Punchinello lays claims to its simplicity
(which he has yet to describe) and to its results (which seem to be
elusive) and to its intellectual inheritance (which seem to lack
references). The method is so intuitive (like a CFA) that it defies
description beyond the rudimentary first step of filling a bucket with
mud (and muttered claims of using alligator clips - which evolved more
into the discussion of the comparison/contrast to crocodiles). I can
only suppose you infer the characteristics from the number of steps
you can traverse before you give up hauling it toward the kitchen. 10
Ohms per step and toss in 10 Ohms reactance for each stumble? I don't
need to see the source code for that, thank you (and I already know
the difference between crocs and gators).

Such glaring contrast to Terman's clear and open style.

Which was MY point on inefficiency often present when attempting to operate antennas too close to
adjacent structures - frequently, even apparent non-conductive surfaces will GREATLY inhibit
radiation ability of such antenns - sure, you probably WILL make some contacts, just at a rather
POOR level of efficiency!

I'm puzzled as to why ANY such device is "needed" - I operate my 706 into a screwdriver, and also an
SGC 230 autotuner... I merely place the function switch in the AM position, key the rig while
monitering SWR, and awaaaay we go! WHY the "need" for some "special" device?

Nobody disagrees. Question is, would a short, loaded vertical
(screwdriver) close to an adjacent structure (a MH) be as efficient as a
full-size horizontal dipole or inverted L, close to the same structure?

Well, 10 watts does cause less interference than 40 watts.

Hi Bill,

You likely will have no problems or noise with your VHF/UHF radio in
your truck. It's always advisable to run 12v lines directly from the
battery through the existing holes in the floor in front of the seats.
The antenna coax can also feed through these holes and brought up
behind the rear window to the antenna.

Although some hams report HF radio noise problems in the Fords, I've
had little in my 2000 4.0 4X4 Ranger with two HF radios (FT-757 and
TS-130SE) . The antenna is mounted on the right rear, which might help
(plus those receivers are not overly sensitive, I guess).

Noise blankers also help, although HF mobile installations probably
always involve some noise (if nothing else, from other vehicles). If
the QSO is all that important, one can always pull over; it's safer
that way, too <g>.

What kind of kites do you fly? I love my Jam, Stranger, Maestrale and Psycho which all keeps me smiling. I love to take out my QuadTrac when I wanna go flying myself!

As well as I love flying them in 'my horses pastures'. Its funny to see the horses, all three, folowing them like people watching a tennis game, left-right,up,down and so forth!

It's hiliarious.

PS: My take on the HOA's out there. Those neighborhoods are the same as the 'projects' with each home which looks the same as the other. Instead of a $20,000 home they are $200,000 homes. The thing is, at least the $20,000 home can paint it if they wish and whos to complain!

Source record: 148988

Fachman wrote:
"Shouldn`t be also some multiplier?" (Length as well as "size")

Yes. For a particular frequency and for a particular coaxial cable, the attenuation is most often specified as a particular number of db per 100 feet.

Loss in coax comes from resistance which is a function of frequency due to skin effect. Larger cable has less resistance. Longer cable has more resistance. Conductivity is usually about the same for most cables. Most use the same conductive material, copper. Slight differences result from platings used (or if a different material is used) and from if the conductors are solid or stranded (braided).

Loss in coax also comes from dielectric material. This loss is a function of frequency also. The more times per second the signal nudges the molecules of the dielectric to move about, the more loss is developed. Some dielectrics are lossier than others and some coax uses more of this lossy dielectric than others do. For example, solid dielectric tends to be lossier than foam. Air occupies a lot of the space in foam. Foam dielectric tends to be lossier than Heliax, in which the dielectric is solid but only occupies a narrow spiral space around the center conductor. Heliax tends to be lossier than rigid air-dielectric coax because less dielectric is needed to keep the center conductor centered in rigid coax.

Common sense should indicate which coax will be more efficient.

Best regards, Richard Harrison, KB5WZI

A way to get the screwdriver further away from the motorhome structure
is as recommended to me by Don Johnson, W6AAQ. I mounted the base of
the antenna on the driver's side at about the point where the body
started sloping back for the windshield. This kept the antenna well
away from the structure. My ground was the steel frame of the
Winnebago in the engine compartment, right behind the mount. Used a
6-1/2' whip while underway, and a 9' while parked. Got out like
gang-busters with that setup. Of course this won't work if the
motorhome is built like a box front and rear.

Source record: 148987

It is much more convenient. You just push the tune button and adjust the screwdriver up or down. With your method you have to set the mode to AM, key the rig, adjust the antenna, then set it back to SSB (assuming that's what you are using.) A lot more distractions for the driver. And the 10 watts causes a lot less QRM than the 40-watts you are using. Of course you can always turn the power down first, but then you have six operations to perform.

Amen. They're slapping these $600k "cottages" on single acre lots.
It looks like a bunch of overgrown suburban houses scaled up so that
they're still too close to one another. Don't get me wrong, these
houses are quite nice inside. But I like having enough land around my
house so I can hoot, holler, shoot spuds in the air and keep animals
without annoying my neighbors...

I spent a couple of years of spare time studying the issue of the self impedance of antennas. I have a pretty large pile of professional papers on the subject, and have in my library five major antenna texts, plus a number of minor ones. None of these make any mention of "explicit algebraic expressions deduced by fundamental engineering reasoning which any competent electrical engineer should be able to do for himself." It appears that Reg, once again, has singlehandedly developed a simple method never before discovered by generations of engineers. As one of the incompetent engineers, at least I'm in good company along with Kraus, Johnson, Jasik, King, Harrison, Jordan, Balmain, Schelkunoff, and many other "waffling old wives".

The ultimate test of any calculation is its ability to produce results consistent with reality. The set of measurements most often considered as a standard for evaluating theoretical methods is the one in Brown and Woodward, "Experimentally Determined Impedance Characteristics of Cylindrical Antennas", Proc. of the I.R.E., April 1945. All theories purporting to predict the self impedance of an antenna have had to run the gauntlet of comparison with these measurements. Certainly, many approximations have been and can be made, all with varying accuracy. It's always important to determine what the degree of error is and the range over which the approximation is valid.

Using "fundamental engineering reasoning" is fine as long as the reasoning is sound and it's based on valid assumptions. The test is whether it produces verifiably accurate results. If Reg has indeed come upon a nice, neat closed form soultion for this problem, he's accomplished something that no one else has been able to do in nearly 100 years of searching. A professional paper would certainly be in order, showing calculated results and their comparison with Brown and Woodward's measurements (or other measurements if of demonstrably comparable quality). I look forward to reading and learning from it.

As Vito says, the mounting pole material is unimportant because this is a neutral point. However, remember that the J-Pole is a balanced antenna so you need to form a choke balun with a few turns of coax at the feedpoint.

Hello,
I am biulding a Jpole antenna but I have a few questions:
My Jpole is according to next shematic, but I don&#65533;t know if it is correct, any one can help me.
In the web shematics the 3/4 wave section is conected to 1/4 wave section with conductive material, is that correct?
And the continuation of the 3/4 wave what is the function, in the shematics is about 20inchs, is that section only the support or is it part of tha antenna?
Can anyone give mee sites that explains all details in construction of this antenna
Best regards

I mainly want it for home use. I don't change freq enough when mobile to worry about it. For me , it would come in handy when I'm tuning my tuner, say when on 160m. Sure, I can put it on AM and test with the full 40 watts no problems, but many times I'm on the CW portion of the band, and hate to have audio or noise on my carrier. I've usually got TV's etc going in the background. So I end up usually using RTTY and going into the menu and cutting it back. And yes, I know as Cecil says, that you can test with full power and let the protection circuit cut back, but I'm paranoid. That makes me nervous at 100w out. Fairly new radio too... I like to baby my finals. They get enough abuse with my normal operation. :/ MK

> full-size horizontal dipole or inverted L, close to the same structure?
> KA3DWW

Depends what band, time of day, distance, etc. Also how far the dipole was from the metal body. Like Gary said, lots of variables. It's quite possible that with a decently working setup that wasn't overly killed by the coupling to the car, you could outdo the screwdriver on a NVIS type path. Say 40m in the day or 80m at night possibly. But then you have to think about having a 65 ft dipole strung on a car. Maybe loaded if needed. I'm not sure if you mean moving or not at this point in the thread. On longer paths , higher bands, or late at night on most any band, I'd put my money on the screwdriver for anything over about 800 miles away. The reason I say this, is my mobile antenna on 40m, outdoes my home dipole at 35 ft or so. But it only does it at night on fairly long paths. From Houston to Fla. on 40m, appx 2 AM, the mobile antenna won every time we tested it against the 35 ft high dipole. And no, I wasn't expecting that to be the case...But it happened about 5 times in as row. In a case like yours, there is only one way to really find out. Try it. Probably the easiest way to test at home to compare would be with a FS meter. You can't really go by on the air reports unless you can A/B them with a switch real quick. MK

Yes!
There has been a change over the past (almost) 50 years. When I was an undergrad, the only women to graduate in engineering were better than the men - intellectually and emotionally. When I started to teach electrical engineering, the women were near, or at, the top of the class.
I am delighted to report that women now graduating extend from the bottom of the class to the top of the class.

Think about the significance of my observation.

2818. Re: CC&R's and antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-08 05:12:44 UTC
From: K4JDP@webtv.net
Message-ID: <2492-3C635E4C-7@storefull-132.iap.bryant.webtv.net>
Source record: 149005

The last neighborhood we lived in had CC&R's. They kept changing them at each HOA meeting.

First, only vinyl-covered chain link fences
no higher than 4 ft.
Then, shadow-box fences, no higher than 6ft. Wood molds here in FL very quick just like the roofs.

First, no boats allowed in the neighborhood.
Then, when shadow-box fences went up our next door neighborhood buys a boat and backs it into his backyard behind his moldy fence.

First, no more than 2 pets per family.
Then, no limit on pets. Our rear neighbor
gets 4 yapping chihuahuas. Yapped all night long and kept us awake for 3 years.
First, no outside antennas. Had to put a dipole in the attic.
Then, dish antennas allowed outside for TV reception. Then they went nuts. Wrote a new covenant prohibiting any ham radio or CB radio transmitter from being brought into the neighborhood by homeowners.

This didn't affect my operating since I already lived there. We moved out because of all the changes to the changes and the continual increase of HOA dues and continual harassment by the "property manager" hired by the HOA. "No wet bathing suits in the clubhouse, no flip-flops in the clubhouse, sign-in before using the pools, sign-out before using shuffleboard equipment, no kids allowed in the clubhouse without parents. ad nauseum."

I mailed a copy of the CC&R's to the ARRL to show them and the FCC just how far one HOA has tried to go in an area they have no authority over (namely prohibiting ham radio transmitters in the neighborhood.)

There are NO new homes being built in developments without CC&R's anywhere in this county. We have looked at building our own place on a lot and we don't like what we see in those areas, namely huge messes by messy people.

We have now found a development which does allow outside antennas no higher than 10 ft. above the highest point of the roof line. Our home will be a 2-story.

Fachman wrote:
"--heard that its size must be a multiple of the length of the radio wave for best results."

The intention of Fachman`s source is a mystery. Don`t know of any transmission line where "size" must be a multiple of a wavelength except as a phasing or matching tool, a circuit element, or as a tuned circuit.

The cross section of a waveguide has minimum dimensions with respect to wavelength. The longer dimension must be greater than 1/2-wavelength to allow propagation of a wave in the waveguide. This is a low-frequency cut-off. Waves just above the cut-off frequency have too much attenuation and waves too much above the cut-off frequency can propagate in too many modes and this is problematic. So, waveguides are sized for a particular frequency range.

There is no low-frequency cut-off for coax. In coax, length is not critical if a matched load is served unless one of the other uses such as a circuit element is being served.

Another use of coax is as a transmission line which will not alter any impedance presented to it. This requires a phase change of 180 degrees (1/2-wavelength) in the coax, or some multiple of 180 degrees. That may be Fachman`s "size".

Another possibility requiring some particular length of coax as a fraction or multiple of wavelength would be for impedance matching or producing a particular phase relationship, as already mentioned above. Without more information we can`t know what was intended.

Best regards, Richard Harrison, KB5WZI

Hi all.

A few years back I had a mobile antenna mount that was made by Hustler. It used a hole in the fender like a factory AM/FM antenna would use. The mount had a uhf connector on the feeline side and a 3/8" female hole on the antenna side. This was just an antenna mount, no electronics involved.

I totaled the van, and did not take the time to remove the antenna mount. I thought I could find another one easily, but it's been 5 years years now and I haven't seen one since! Can any of you recall (or look up in an old catalog) the part number of that device? Then I would at least know exctly what I was looking for. It would be greatly appreciated.

Thanks,
John Breland

Roy, Reg, et al:

I know I sort of "trashed" Reg up the thread a ways for not sharing his "fundamentals" with us.

However Reg's neat little computer programs give pretty good results in comparison to actual
measurements, etc... So what is he really doing?

To be fair to Reg... he did share with us a somewhat veiled peek at his methods of calculating
R and X, for these antennas which, if I can read between the lines of Reg's allusions, are apparently
based upon TEM transmission line models rather than upon antenna field models.

The antenna guru's and the textbooks and papers to which Roy refers simply do not consider
this as an "antenna" problem, or more likely they don't consider it as a valid approach to solving an
antenna problem cuz it uses Kirchoff's laws with voltages and currents rather than some integration of
Maxwell's field equations.

Heh, heh... antenna jocks can outsmart themselves by insisting that there are no voltages only "line integrals", etc...

Reg apparently models these antennas from a circuit parameter [Volts and Amps] perspective as
TEM transmission lines utilizing distributed RLCG models from first principles. i.e. from calculations
of static capacitance, static resistance with perhaps some skin effect formulae factored in plus
inductance per unit length, as opposed to using a field equation perspective.

The only thing that would be missing from such a first principles analysis of an antenna as a transmission
line would be the radiation resistance of the antenna.

At least, I can't see any way to derive the radiation resistance from the TEM transmission line equations!
Apparently Reg has some way of separately calculating the radiation resistance [Is this where he introduces
some empirical curve fitting? I don't know!] and then apparently he just adds this radiation resistance to

the TEM transmision line model in a uniform distribution of the radiation
resistance along side the
distributed thermionic resistance R.

Such formulas should be pretty straightforward...

Reg, is this what you do in your programs?

Heh, heh... I'll bet he won't tell.

Mark Keith wrote:
"I think Richard Harrison once said he knew a guy that tried them."

Phil, W1DBM had less than dazzling performance from his ground mounted parasitic array. He then tried driving all the elements and it worked exceptionally well. Hello Australia? and they came back every morning in abundance.

Roy Lewallen suggested that the driven element which has too much resistance in a parasitic array may cause pattern shrinkage, and the parasitic element which has too much resistance in a parasitic array may cause wash out of the directionality. Phil probably thought he suffered from both problems until he drove all of the elements. His problems then were history.

Best regards, Richard Harrison, KB5WZI

Marty,
How about some 300 ohm twinlead, the 20 gage stuff is usually in a
translucent jacket which might be easy to conceal. The guru's could
speak better than I as to power handling in a wire of that gage; you
could have to keep your power lower than in the past but at least
you'd have something.

Good Luck & 73,

Source record: 149012

Hi,
if the RF cable is matched on both ends, it carries a travelling wawe only. Both the attenuation and the dispersion increase with length, the dispersion is usually negligible. Thicker conductors have less unit attenuation; gas dielectric (air) has less unit attenuation than a solid one.
If the cable is not matched, a standing wawe appears together with all its effects. The parameters of the cable seem to change periodically after half of the wawelength (with shortening coefficient). This is not the matter of the cable, but of the poor matching.
Coaxes have one more limitation: only the TEM wawe should exist inside. The limit frequency of the next mode (perhaps TE11) is considered as the upper limit for the coax. The thinner the coax is, the higher this limit.

> Lost QRP'er

Dunno, sounds like you bought the wagon before the horse. You normally wouldn't use a 4:1 balun with either one of those antennas. Or at least I wouldn't. But if you want to try, for a dipole just hook one side to hot, and the other leg to ground. Normally, a long wire would be hooked to hot, and the ground side grounded to earth. You don't mention the feedline used, so hard to tell what you have in mind. Are you using a tuner and ladder line? Does the tuner already have a 4:1 balun in it? IE: provisions for a balanced output? If you are using coax, you would want a 1:1 balun for a dipole. I normally wouldn't use a balun at all on a long wire, unless it happens to be a 4:1 already in a tuner. But than again , normally I wouldn't even use a long wire/random wire. I'm not that crazy about them. All you need to match a long wire is a simple L network tuner. A MFJ 39.99 special will do the job. You don't need a balun at all on a coax fed dipole. But it's good practice to use one to reduce currents on the shield of the coax. You don't want it acting like part of the antenna. MK

2828. Re: R & X for simple antennas

Schelkunoff uses entirely transmission line principles for his analysis. He first shows how a conical antenna can be analyzed as a constant impedance transmission line, then derives factors to account for the equivalent change of impedance with distance from the source that a cylindrical (e.g., wire) dipole represents. The process is nicely summarized in a series of articles in Ham Radio magazine beginning in April 1977 by Joseph Boyer titled "The Antenna-Transmission Line Analog".

Heh, heh. Boy would you be surprised. The people around here take pride
in their houses and property. They just don't need a group of control freaks
dictating to them how to do so.

The kids may need spanking, but that is pretty much true anywhere in the
US these days. If you punish the kids - you get accused of child abuse.

Unfortunately, HOAs DO have authority over outside antennas, if they wish.
These are not local or state governmental regulations which the FCC has
partially preempted. They are civil contracts that you sign when you buy
a home in the area - and sometimes even if you refinance your house.

The HOA can sue you in civil court to force you into compliance.

The last I heard, the FCC has refused to override the CC&Rs, even though
there have been a number of requests that they do so.

> There are NO new homes being built in developments without CC&R's

I wouldn't want to live in a crowded development anyway. I would rather
purchase a much larger piece of property elsewhere - and end up paying
the same or less for a comparable home.

Alrighty.... so then what I am picking up from this message is that electrically or RF speaking, as long as it is a radiating type of material, that is all that matters?

The concerns I had with choosing a material to experiment with was in relation to:

Cost
Strength/Durability
Weight
Availability
Ease of use/tools necessary to manipulate

I believe copper is probably the best candidate, based on the above factors. But was curious about others. Never hurts to learn more eh?

Right... again, my concern was, is that particular part a mechanical part of the antenna or electrical/radiating part of the antenna. The sole purpose of this antenna would be portable/emergency type of set-ups. Since there is a variety of materials that I could use to make the bottom part, that is why I posed the question. No where have I found content that addressed that fact.

2839. 300ohm twinlead matching section?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-08 13:33:18 UTC
From: Marty <nfn04028@naples.net>
Message-ID: <ysQ88.19586$Hb6.1699409@newsread1.prod.itd.earthlink.net>
Source record: 148826

The only place I have to put up an antenna (stealth type) will accommodate only about 25ft of wire and it has to be an inverted V configuration to avoid proximity to a lot of metal.

With 75ohm coax to the tuner I can receive a surprising number of stations on 20 and 10 meters, but not unexpectedly the SWR is out of sight if I try to transmit.

Can I put in a section of the twinlead to get this thing to match on 20, as is done with the g5rv? If so, how long should it be?
(I know ladder line is usually used, but it is too visible. And I have translucent twinlead.)

Any suggestions would be appreciated.

Depending on the tuner, i. e. if it has an output for balanced line,
you might consider running twin-lead all the way from the tuner to the
antenna. I'd expect that your short V antenna could then be tuned at
least on the bands above 10 MHz. This even works for a 7 m random wire
folded three times by almost right angles, working against a lousily
earthed balcony railing (as is the case for my "main portable QTH").

Any antenna is better than no antenna.

Victor -
Try this site: http://www.packetradio.com/jpol.htm I've successfully built this antenna, using the alternative feed method (SO-239) and mounted on a 10 foot tube of schedule 80 PVC; cheap! Also, there are numerous discussions as to construction a simple choke balun at the feed point; about 4 small loops of coax. However, I've tried a choke balun on this version of the J-Pole and it made no difference.

Good luck & 73's

That's not much of an excuse. Try Amateur Electronic Supply, HRO and other major ham supplier places. They sell all the basic ham books, and they will accept a check by mail if you don't do business by credit card.

> Any business with the ARRL
>requires a credit card.

That simply isn't true. You can order ARRL publications by mail, sending them a check or money order.

The ARRL Amateur Radio Handbook and ARRL Antenna Book are two references any ham should have on his bookshelf. They also have books on vhf antennas, such as the j-pole you're building.

Look at the pictures on <http://www.n7qvc.com/copper.html> Note that
there are no nonconductive parts like in your schematic.

> In the web shematics the 3/4 wave section is conected to 1/4 wave section
> with conductive material, is that correct?

Yes. In a "copper cactus" the same copper pipe is used for the whole
antenna.

> And the continuation of the 3/4 wave what is the function, ...

AFAIK, only to provide mechanical support. As K0YCN pointed out, you
should have a few turns of coax at the feedpoint to form a balun.

Roy:

Thanks for that HR reference, I remember that now, it was a good series.
As of course was HRn Magazine in general (Sigh!).

As you know, all distributed networks, antennas included, have an infinity
of
singularities. For practical purposes, in any sufficiently narrow frequency
range,
say over an amateur HF band, to get good impedance results, it may only be
necessary to model, say one or, only a few of those singularities.

To a first approximation the input impedance of such an antenna is closely
modeled by a series RLC circuit. The problem is to determine the values
for R, L and C in terms of the antenna physical characteristics...
resistivity,
length, diameter, height, frequency, surroundings, e.g. nearby ground
planes, etc..

A short analytic formula for antenna input impedance even taking into
account
secondary effects could be to model the antenna using say the first couple
of
singularities. i.e. model the the antenna using only 7 parameters with some
sub-parameter modifiers, as three subnetworks in parallel namely:

1.) The static capacitance of the antenna [Co] in parallel with...
2.) A series RLC network at the fundamental [R1, L1, C1], in parallel
with...
3.) A series RLC network at the second harmonic [R2, L2, C2]

[The R's would need to be composed of three components: the DC wire
resistance, plus a skin effect modifier, plus the radiation resistance at
the appropriate
frequencies, etc...]

Do you know of anyone who has done this? Schelkunoff ? Others?

Perhaps this is what Reg does. I wonder?

Download Reg's program and check it out... it's not very *big*. Which
is true of all of Reg's *free* software, heh, heh...

Of course all I have to do is fire up your EZNEC and run an NEC FEM analysis
right here on my laptop to get "exact" results from a numerical
integrator...

For $99 you can't beat that!

Just can't carry it around in your head, or on the back of an envelope.

Compare Reg's program with the size of the EZNEC executable!

Why open a walnut with a sledgehammer?

A halfwavelength of 300 ohm, 0.9VF twinlead on 14.2 MHz is about 32 feet.
So feed your Inv-V with a 32ft piece of 300 ohm twinlead and check the
SWR. It should be approximately equal to what you have now. Then:
1. Chop one foot off the 300 ohm twinlead and read the 20m & 10m SWR.
2. If the SWR is not satisfactory, repeat step 1.

You will find an optimum length for 20m and a different optimum length
for 10m. If they are close to the same length, take the average. If
they are not close to the same length, choose one band over the other.

Should have mentioned that my tuner doesn't have a balanced output; hence
the use of coax and need for the matching section. Otherwise I would have
used all twinlead as suggested.

Ryan...I use a piece of PVC for my Jpole portable support, works FB. The fixed mount is a steel pipe on which the Jpole just sits, no fixed connection. For portable use, the PVC is what I use. I will be going to a mast....but it will make no electrical difference as to your question. Nice simple antenni, go for it. Lemme know if you have any further questions at kg4gsc at qrz dot com.

Happy Hamming!

Roy Lewalen wrote:
"None of these make any "explicit algebraic expressions deduced by algebraic reasoning which any competent electrical engineer should be able to do for himself"."

I think Reg was the originator of that burr. That may be a stretch, but Ed Laport is fairly easy to follow and he works out radiation resistance for vertical antennas and gives formulas as well as tables and graphs. Arnold B. Bailey in "TV and Other Receiving Antennas" gives a plot of 1/2-wave antenna feedpoint resistance versus distance from the center of the rod for the feedpoint attachments. It is specific to an L/D of 300 for the rod. The feedpoint resistance varies from zero ohms where the attachments are shorted together at the center of the rod, to 1000 ohms all the way out to the ends of the rod.

The formula Bailey gives is:
Ro = Rmax times sin squared (pi A/2)
A is 1/2 the distance between attachment points in terms of wavelength

UMMmm - has no one noticed that you don't HAVE to key the 706 at FULL power - *I* simply
reduce
power manually to 10 watts or so, and tune away - and I dern sure don't need something
plugged into
the backside of the 706 to do it - it's a single push of the button and dial the power
level I want.
Especially handy with the Ameritron 500 watt amp I use, since I sometimes need/want
different drive
levels, demending on what antenna is in use at the time.

Mike Luther wrote:
"Polyphaser has or had a web site devoted to the science of protection of things which must remain working."

Get all the free information you can from Polyphaser and others. They have some good information. But, Polyphaser is really devoted to selling Polyphaser.

I`ve worked for years in many broadcast stations and many more years working with industrial radio stations. Of these hundreds of stations, none had gas tubes across the antenna feedlines. None of these 24-7-365 operating stations received lightning damage of consequence, though many were solitary in their positions on the highest sites for miles around and often hit by lightning. They just kept on operating.

We found the solution to our lightning exposure, besides the usual practices, was broadcast tower lighting chokes in every wire in the power service including all grounded wires. This prevents an instantaneous difference of potential from causing a large current flow through protected equipment. It gives arrestors a chance to work. It allows the earth around the station to momentarily rise to some high lightning induced potential without instantly forcing a huge discharge through your equipment to the powerline which may very well be connected to earth at a very different voltage.

Think about it. Constant operation in hundreds of stations at diverse locations on the globe all with no damage.

Best regards, Richard Harrison, KB5WZI

Hello Mike,
On a related note I have a sketch of the inside of the R-7 "black box"
with layout and component values on my site. A larger version of the
image is also available for download. Just search from my homepage for
R-7

> You don't want it acting like part of the antenna. MK

Well I bough the 4:1 balun for my LDG Z-11 QRP autotuner. I feed the balun with RG-58. I bought the balun under the recomedation for long wires. By basic station set up is a Yaesu Ft-817 to the Z-11 QRP autotuner to I am hoping the 4:1 balun for use with longwires. Kinda a backpacker rig. Make sense?

2864. Co-linear v discone

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-08 20:27:10 UTC
From: "Derek R. Smith" <derek@multnomah.demon.co.uk>
Message-ID: <TRH$d9CeSDZ8Ewzf@multnomah.demon.co.uk>
Source record: 148851

I am looking to buy a new aerial for use with a NRD 525. (Yes I know the audio could be better but the RF performance seems pretty good).
I listen to amateur bands mostly (50, 144 and 432Mhz) but also like to listen to other transmissions in the aircraft and adjacent bands.
Below 30Mhz is no problem as I have a suitable 'long wire' and balun.
Location here precludes the use of several separate aerials and I visited the local Ham radio shop to buy a discone. I was advised that a co-linear would perform better on the ham bands for which it was designed, and would be no worse at the other frequencies in between.
I am now confused because I know the discone will provide little or no gain, but it should be relatively flat across the frequency range of interest.
A co-linear will give gain at its design frequencies but surely there will dips in the performance in between and these dips are likely to provide inferior performance to a properly designed discone?
I have also seen advertisements for a "Royal Discone" that claims to provide gain at the three amateur band frequencies and enhanced discone performance everywhere else. Is this a discone, a co-linear or something else? Can the claims be true?
I'd be grateful for some opinions from any of the many aerial/antenna experts out there.
TIA
Derek

Source record: 148852

Hi Chris:
I prefer the crimp on type, but then I have the tooling to do it. The problem is that the tools to crimp SMA connectors are not interchangeable with other brands of connectors. So if you buy AMP SMA connectors you need a AMP crimp tool. Also you will need a different crimp tool for each size of cable. This is not a problem with the solder type but they are harder to put on.
My advice is to follow the manufactures instructions "EXACTLY", close is not good enough.
It might be better if you only need a few cables with SMA connectors to buy them from some supplier that can do the job right as the crimp tooling is costly and the center contact is tough to solder if you are not skilled at soldering.

However, if you read the details, this only seems to apply if you have
eQSL print and mail a physical card to you by postal mail (and only
in the US, at least at this time) at a cost of $1 per card ... this
seems
to defeat the economy of eQSLing compared to "the old way." It also
would seem to put eQSL at an economic disadvantage compared
to the ARRL's proposed "LOTW" ... if I were eQSL I wouldn't be so
happy about this. (I'm not complaining about eQSL's charge for
printing and mailing a card ... that doesn't seem unreasonable for
the service ... I just view the process as an unnecessary step which
adds unnecessary cost ... to the disadvantage of the eQSL folks.)

DISCLAIMER: I am NOT affiliated with eQSL in any way and I'm
not really an awards chaser ... for me, it's just the principle of the
thing, where I see the eQSL folks as having come up with a good
idea that can save hams a great deal of cost on QSLing, and it
appears to me that the ARRL is making things tough for them in
ways that I view as arbitrary and unnecessary.

Hello Carl,
This decision and news was just released so there are a few loose-ends yet....soon it will be world-wide. The granting of permission for eQSL - DXCC cards acceptance was for any and all cards. The nice people at eQSL will be adding world wide capability very soon...

DXCC qsl'ing is now -cheaper- and -faster- than ever....a huge and bold step in the right direction.

Hi Jim,
To determine antenna reactance you can use a transmission line
approximation, with:

Zo=60[ln(H/a) - 1]

where
Zo=transmission line characteristic impedance
H=antenna wire length
a=wire radius.

This is for a vertical (unbalanced) monopole and is 1/2 of a dipole's
(balanced) reactance. It is independent of ground; i.e., assumes free
space.

Then you can use:

X=-Zo/(tan(theta))

where theta is the electrical length, equal 360(H/lambda) degrees.
You can also throw in an extra 5 degrees for the first quarter wave
to account for end effect.

This seems to get you close enough and seems to agree with NEC2 to
within several percent when I have used it, even for multiple
wavelengths. The Zo equation is in an old printing of Jordan, chapter
14, and I've seen in in some of the ARRL pubs.

Radiation resistance is more difficult to calculate because it
(practically) depends on conductor losses and ground effects.

Hi Folks,
I'm interested in a Diamond SG7900A, dual band mobile antenna. I'm thinking about mounting it high (atop the rollbar) of my Jeep but I'll also be strapping a canoe up there from time to time as well. I've seen the tiny picture of the "one touch fold over design" and am curious if it's a good choice or should I look for another mount point.
Has anybody had experience of the fold over mechanism corroding or popping downward under road conditions? I'd appreciate general impressions or personal experience opinions on the fold over design as well as the antenna in general. I'd also appreciate thoughts on such a high gain antenna in hilly (not mountainous) terrain. Feel free to add any other considerations as the thread strikes you.

Hi Derek,

You have to be careful with discones. If you have any concern about
the launch angle from one, you want to stay within a 3:1 tuning range
of the lowest frequency. Some discones can tune over a 10:1 range,
but at higher frequencies, radiation starts to steer straight up.

Derek,
If you want one antenna to cover more than one band, I think I'd use the 'dis-cone' which is designed to work over a large frequency range. A 'co-linear' antenna would have gain, but only on a fairly narrow frequency range. On other than the band(s) it was designed for, the co-linear antenna wouldn't offer any benefit over the dis-cone, and may not perform as well.

Source record: 148865

Gary - Think about it for a minute. Assuming a 706Mk II on SSB.

Your method, and not necessarily in this order:
1. Push (Mode) button 3 times to get to AM.
2. Assuming 706 is not on Q1, Push (Display) for 2 seconds to select
Q1.
3. Rotate main dial to select the desired output.
4. While steering with your knees, hold the mike button down to
transmit with one hand, and move the screwdriver up or down for
minimum SWR with the remaining hand.
5. Rotate main dial for maximum power (or whatever.)
6. Push (Display) for 2 seconds to get back to the display you were
in.
7. Push (Mode) button to get back to SSB.
8. Start transmitting.
Hope I didn't forget something.

Method using a little $10 or less plug for the back of the 706.
1. Push (Tune) button.
2. Move screwdriver up or down for minimum SWR. (Note one hand still
free to steer with.)
3. Start transmitting when tune signal drops out.

Don't you detect a little difference in the amount of operator
intervention?

Of course with my method (using AM-COM controller), I just push the
(Tune) button. :-)

Except for television and small (<=1m) dishes. That was enabled by
the Telecommunications act of 1996. http://www.fcc.gov/telecom.html

I believe it was section 207, and the FCC has issued several
rules or revisions thereof implementating that section. Eg:
http;//www.fcc.gov/Bureaus/Cable/Orders/1996_TXT/fcc96328.txt
II.5.(a)

Some additional rule making went into effect last fall, IIRC, adding
internet access antenna of similar size to the allowed list.

But the inductance of the balun is unlikely to be 10K ohms. If one
is driving an impedance of 1000-j1000, for instance, the typical 4:1
balun is essentially abused and relatively nonfunctional.

The reason I posted the suggestion that I did was that a novice at all this is probably going to be technically engulfed in, "Gee, what's all this here?", in trying to accomplish this with what seemed available from the way the question was posted!

You are totally correct in what you advocate in my view. That accepted, if one can spend a relatively few dollars with a bolt-in product, some copper strip, and not think much about frequency of coils, how they are connected and such, the fair degree of protection seems a good first way for a novice to contemplate. Find the parts, Polyphaser or el cheapo, and then go radiate!

Then, as one's interest builds, one's dreams build with it, and one has the satisfaction of looking up in the sky and saying, "Gee, look what's out there!", the real professionalism which you do advocate and exhibit here for all to see will also take hold Richard. There are many

antennas which I would dearly love to build and use, but are out of my reach. But second place or third place is far from nothing, so how to stay in second or third place is worth while knowing .. that's all!

--> Sleep well; OS/2's still awake! ;)

CAM, the 756 PRO is much more radio than the 746 PRO which in turn is heads and shoulders above the original 746. The disadvantage of the 756 PRO is that it doesn't have two-meters like the 746 and 746PRO.

For the $$, I vote for the 756 PRO hands down.

I suppose my resistance to that "tuning gadget' has lots to do with the fact that I *rarely* am
doing any antenna tuning while the vehicle is in motion - I usually settle onto a favorite section
of the band, and if I later want to change, it's usually during a "pit stop" anyway...

Well, that's certainly the best thing to do. If you ever get an
Am-Com you will find it tunes so easily that tuning underway is not
much different than using a cel-phone. Of course they aren't always
safe to use while driving either. Suppose it depends a lot on the
person doing it. I have been operating mobile for 51 years, and have
never found it to be too much of a distraction. YMMV.

Uh, thats what I'm trying to get away from. Instead of switching the mode, then going into the menu, dialing it back, exiting the menu to see the SWR meter,tuning,back to the menu to turn it back up, and then switching back to the desired mode, I click one button. Maybe two if I have to switch modes. I hate having to get in the menu every time to turn the power down and back up. You have to exit the menu for the SWR meter to work. So that mean twice to the menu for each tuning. I'd much prefer NO going to the menu at all. MK

2890. Re: CC&R's and antennas????

Atually, the area I live in is very nice, but really just a housing tract. There is no home owners association, but there are CC&R's. I guess the only way to enforce them is through individuals taking other individuals to court.

I am still not sure what I am going to do about my antenna situation. I have talked to a few neighbors that don't seem to mind the idea of an antenna, but everything is still up in the air. Meanwhile, my IC746 sits by on my desk waiting for use.

James

The OTHER thing I shoulda mentioned, is that I don't use the SWR reading on the 706 - I use an
outboard field strength meter that sits slightly above and behind the detachable faceplate, which is
itself mounted on the top edge of my trucks instrument panel. Thus, it removes several steps in the
not-too-complicated procedure of antenna tuning... But that new Am-Com tuner sure looks slick - had
a nice chat on 20 meters with the inventor/developer of it - got all the nitty-gritty details, and
can't wait to get my quarters saved up to buy one! :-)

An issue came up about tall structures ADJACENT to airport runways and
having done some cursory research, I'm seeing that this is often a
locally controlled matter. I'm seeing things like a 100' tower within
2500' laterally from a runway are prohibited in some areas.
I'd appreciate some accurate references as to height vs. distance
dictated by the FAA in absence of any local regulations.
Any help or links would be appreciated.

Check the FCC and FAA web pages.

Even in areas where there are restrictions, exceptions can be made,
with sufficient lighting and proper delays to get the notices published.

Of course, if your antenna would be close to the standard glide path on
an approach, your options are very limited.

At the airport I used to use, there was a commercial radio station. If
I recall correctly, each tower was around 350 feet tall. It was only
about 1000 feet off to one side of the runway.

It's nice but seems to be overkill to me. The tuner is almost as expensive as the screwdriver antenna. Somewhere I read about a screwdriver tuner that put out an audio tone, high for high SWR and low for low SWR, so a ham could listen instead of watch the SWR meter. I added some components inside my Daiwa SWR meter that removes power to the screwdriver motor when the SWR goes low. It uses no more than $10 worth of additional parts inside the SWR meter.

Jay,
Something you might try, with the coax feed line and a
long wire or random wire antenna is to use a ground stake
for the 'other side' of the balun secondary. If the tuner
doesn't 'like' the match on any particular band, change the
length of the long/random wire...
'Doc
PS - You can use the same basic set up without the balun,
probably never know the difference.

Barry,
Wish I could tell you how they work, but unfortunately
I don't have one. There were at least one or two articles
about a simular device for mobile antennas in very old QST
magazines. As a guess, I'd say it was 20 years ago (about).
A Collins surplus variable inductor, couple of servo motors,
and a sensing network from a 'remote' SWR meter were used
to keep the SWR constant (sort of). The 'ASAC' controller
looks like it would be much easier to live with.

2905. How ground Tail pipe?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-09 18:32:46 UTC
From: Greg Knapp <gknapp@freshrain.org>
Message-ID: <iXd98.810$1F2.18606@sea-read.news.verio.net>
Source record: 148791

Could you share your experience with me? I have tons of ignition and other types of noise (S-8 average on the IC-706) coming from my antenna (a screwdriver on a foldover bumper hitch mount), which is located about a foot or two from the tailpipe on my new Toyota Sienna van, making it difficult, and certainly not enjoyable, to work the HF bands.

If I turn off the engine, all the noise disappears. If I disconnect the antenna, again it all disappears, so I know it's coming from the engine and not coming through the dc power or other control lines).

So, I figure it's most likely the tail pipe, being so close to the antenna, and tons of mobile books say to ground the tail pipe in one or more places, or move the antenna. I can't move the antenna, but I don't have a clue how to ground it.

So, I need some advice. How do you actually ground the tail pipe? Do you drill holes in it to attach some copper grounding strap with self-taping screws? Do you hose clamps to clamp a piece of copper grounding strap to it? Do you scrape it to bear metal and then apply that non-oxidize stuff ("butter") they use on beams to keep the corrosion down and the conductivity up? How do you connect the grounding strap to the underchasis of the car...drill more holes? How many straps does it usually take? How long can the straps be and still be effective? How do you seal the connections so the rain, wet, mud, etc., under the car doesn't make short work of it?

In other words, I'm not very mechanically inclined and really getting too old to climb all over under the car...how do I do this as simply, yet effectively as possible? Any advice is appreciated. Is there a commercial radio place that does noise reduction for a reasonable price in the SF Bay area?

Thanks,

Greg, N6GK

2906. Field Day Special - Gain vs F/B

In designing W7EL's "Field Day Special", I notice that several different elememt spacings yield acceptable 2:1 bandwith.

Am I correct in assuming that the narrowest spacings yield the greatest forward gain & the wider spacings yield the best F/B ratio?

I don't have NEC to model the antenna.

> Greg, If your engine block is grounded your tailpipe will also be grounded.

UMMmm - sorry - WRONG!

Any more than a grounded vertical antenna is "grounded" and won't radiate RF...

An UNgrounded length of exhaust pipe is ENTIRELY capable of radiating random RF energy, EVEN IF it
IS grounded at one end - and UNLESS it is additionally grounded at one or more points along its
length, it IS capable of radiating RF energy JUST AS a vertical antenna will!

The method *I* use is to thoroughly expose clean metal somewhere at the midpoint of the exhaust
pipe, then apply a liberal amount of No-ox anti corrosion paste to both the pipe AND the ground
strap to be used. THEN I use a stainless steel radiator hose clamp to secure the strap to the pipe.
Keep the grounding strap as short and direct as possible, leaving sufficient slack to allow for
normal pipe motion. You will likely need to ocassionally recheck connections as over-the-road
corrosion and exhaust heat compromise the connections. Of course, more than one such ground may be
necessary. Don't overlook other potential sources for interference - today's vehicles have MANY
potential sources of interference - I had to totally shield all underhood wiring with aluminum foil
to eliminate interference, as well as liberal bonding of various body elements - but NOW my truck is
ABSOLUTELY noise free!

Bill and Bill:

The controlling document is FAA AC70/7460-2J. The FCC has a version under one of their numbers also. The usual ham criteria is that notification and lighting not be required, and closer/taller objects are permitted, as long as they are marked and lighted according to AC70/7460-1K. Take, for example, the control tower at any airport of any size. However, the FCC has gotten real picky about non-functioning tower lights on structures requiring them, levying fines up to $10,000 per day for violations. I personally know of one NOAV which was issued to a microwave tower belonging to Central Power and Light Co. in South Texas for that amount. It was one which was in a flight path, but was permitted if marked and lighted. Top beacon burned out, nobody noticed, and a FAA guy saw it and had FCC issue the violation notice. They lawyered it down, but still ended up paying a substantial fine when investigation showed it had been off for several days.

Greg wrote:
"---how do I do this as simply as--- possible?"

Your exhaust system is bolted to your engine (manifold). The tailpipe is insulated by a rubberized canvas strap used to keep engine vibration from your car.

Electrically short the final tailpipe hanger with a clip-lead. Make the lead a short and heavy flex-conductor. Use alligator (crocodile) clips on the ends of the heavy conductor.

You can have electrical conducton without mechanical vibration transmission if you keep it flexible. You could bolt a flex strap in place, but a good clip-lead will last forever and is easy to try and leave permanently if it works.

Remember the clip-lead is back there, and it can temportarily get you out of an electrical pinch some time in the future.

Best regards, Richard Harrison, KB5WZI

Hi, I aksed the same question to Cushcraft tech support and here I quote
what I bot back:

"1/2 0f the boom length of the antenna operating at higher frequency is
sufficient for spacing.
The light weight antenna will be on top.
Cushcraft Technical Support"

So put the A3WS on top of the A3S, at a vertical distance of 1/2 the boom
length or the A3S (my interpretation of above).

I just cut four pieces of 1 inch ground braid strap about 12" long, drove down to a muffler shop, and had them braze one end of the strap to various points on the exhaust pipe, and the other end of the straps to points on the frame.

It cost me $15.00 and 20 minutes time to do it. The nice thing about brazing rather than clamping is that the connections are much better electrically, and they won't deteriorate over time from the rain, snow, etc. that gets kicked up under the car.

2919. Re: How ground Tail pipe?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-10 00:04:37 UTC
From: 'Doc <w5lz@icok.net>
Message-ID: <3C65B8F8.CFE81945@icok.net>
Source record: 148805

Greg,
First, try temporarily grounding the pipe to see if
it is the problem. If it is, then it shouldn't be too
difficult to find someone to 'tack' weld a wire/strap to
the pipe and to the frame of the vehicle. If the temporary
grounding doesn't 'cure' the problem, you've saved some
time and money. 'Tack' or 'spot' welding is a permanent
'fix', clamps/etc, are temporary.
'Doc

Web,
Depends on if you mean a true 'Windom' antenna, or one of
the 'Carolina Windom' type antennas. The 'Carolina Windoms's
work comparably to a dipole on the design frequency. Some
change in radiation pattern, but on the whole about the same.
A true 'Windom' antenna requires a very good ground system
and is a vertically polarized antenna fed with a single wire
feed line, 'worked' against ground. Be prepared for lots of
RFI to start with, then improve your ground system more. Works
more or less like any vertical...
'Doc

Dissipationless resistance is certainly abused on this newsgroup. Why the
description was ever invented I can't imagine.

Regarding Cecil's confession, baluns are often associated with (ferrite)
rings. I notice sexual abuse is not mentioned. How often is the dictionary
updated ?

Yeah, and watch this "convenience" see the demise of DXpeditions!
DXpeditions rely heavily on income & donations that is included with the
request for a good ol QSL card.

I hope you advocates of e-QSLing have already worked the rare ones on all
band/mode combos, coz it'll be a different ball game now.

Looking for an Icom AT150 or AH-2a in working condition.

2926. Re: windom antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-10 03:15:52 UTC
From: 'Doc <w5lz@icok.net>
Message-ID: <3C65E5C3.93A58E46@icok.net>
Source record: 148812

Web,
It still depends on how you make the comparison. Since
the two antennas aren't the same 'electrical' lengths on
their design frequencies, the comparison is sort of 'slewed'
to start with. On bands other than what they were designed
for, they probably come out somewhere close to 'even'.
'Doc
PS - I'm not a fan of either antenna, but they do work.

2927. More on Mobile Ignition Noise

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-10 04:14:21 UTC
From: hurstjsj <hurstjsj@gte.net>
Message-ID: <xsm98.3288$ql1.732224@paloalto-snr1.gtei.net>
Source record: 148816

Here are some ideas on mobile ignition noise reduction.

1. Keep in mind that there are probably many ways the ignition noise is being coupled into the antenna system. If one has say, only two equal sources causing an S9 noise level removing one will drop the noise only a small amount (-3db). It's therefore important not to try just one "fix" at a time but to leave all supression "fixes" in until the noise is reduced to a satisfactory level. You can then remove them one at time to see which ones are necessary. Usually the last needed "fix" will result in a DRAMATIC improvement.

2. I added all the usual things under the hood of my Caprice wagon (grounding the hood, the block etc.) with only a small improvement. I then went under the car and added ground wires from the trans to chassis and tailpipe to chassis with only a small effect. When I finally grounded the metal fuel line the noise dropped about 6 S units to a satisfactory level. And no, it wasn't fuel pump noise that was eliminated it was ignition noise on the fuel line and gas tank that was bypassed to chassis.

3. I discovered that the noise on the transmission, tailpipe, etc. could actually be measured with a diode probe connected (by a very short lead) to a DVM. I initially used 1/2 inch wide braid about 6 inches long between the trans pan screws and the chassis. I could actually see the voltage drop change from 0 to several mV as I move the signal side of the probe along the 6 in. length of the braid! This convinced me that the signal sources from the ignition system into the drive train, exhaust, fuel lines are very low Z and it takes a very low impedance lead to bypass these noise conductors (over a wide frequency range) to the chassis. I found that 3 or 4 paralled #16 wires worked better than the 1/2 inch braid. Connections to the chassis were made with 1/4 in. sheet-metal screws.

4. Items under the car like the drive train , muffler and gas tank are a part of the "top electrode" of the car to ground "capacitor". Noise on these are actually in series with part of the car's coupling to ground and are not necessarily "radiated" into the antenna. This would imply that large area noise sources closest to the ground are the most significant.

Any thoughts?

John, KU6X

2928. How do they get the stuff?

OK, gang. I haven't posted a question in a couple of days, but here is today's: I just scrolled through the listings in the ham section of you know where, and I see an awful lot of posts to sell ham gear by people who obviously have no idea what the stuff is. How do they come by this equipment and have no contact with ham radio? I can only think of two ways, neither of which I like. One is theft, the other is estate sales by widows who weren't properly prepared by their ham husbands about how to dispose of the equipment properly. Anyone have a more reasonable explanation of how they get their hands on it?

Nah. They'll just require a "donation" via Paypal before your call shows up on
eQSL's "service."

Just think... you not only need a rig and antenna, you'll need Mastercard too
<g>.

I think I'll stick to green stamps and mail. I like getting 'real' QSLs and I
give the incoming DX stamps to the neighbor girl for her collection.

I hered about a device called antenna tester it is just a
RF-generator plus a SWR measurements .
it is for antenna installation .
i dont know waht is its benifit for antenna installation .
i mean i have static frequency channels(i.e TV channels) and of course
static antenna lenght (i.e fixed)
then what may i gain with that tester.
another question:
i know that a receiving antenna must be in the order of half the
wavelength
. is that apply for a transimitting one ?

I've had one up for 4 years now, it's the full size 160m version. Also during that time have had full wave horizontal loops for 80 & 160, fed with ladderline and the classic 135' dipole, fed with ladderline as well. Also had a couple of G5RV's up at one time as well.

The highest I can get any of them is 65' due to limited tree heights.

On 160 it is definitely better then the loops. On 80 the loop is better for close in. On 40 it reaches out further. The 80m loop is consistently better on 17 and 12m. On the rest of the bands it depends on propagation.

It's a durable antenna using copperweld. G5RV's don't hold a candle to any of them. Wish I had another one for a different orientation in direction ... someday. I'm very pleased with it, my MP loads it without a tuner on all the bands.

> So, I need some advice. How do you actually ground the tail pipe?

Greg,

I have my local muffler shop weld 1/4 X 1" bolts to the tailpipe and the frame. Takes only a couple of minutes and usually costs about $10. They also let me install the straps while the rig is in the air. In and out in 15 minutes. What I use is flexible braid strapping secured under a big, nasty star washer at each point. I use one connection on each section of tailpipe. Seems to work.

2937. Re: Field Day Special - Gain vs F/B

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-10 10:31:04 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C664BE8.62363E3E@eznec.com>
Source record: 148925

As long as you have a current magnitude ratio (I MAG) near 1 and relative phase (REL PHA) near zero, you'll have a good front/back ratio. The gain won't change much with moderate differences in spacing, and it's not very sensitive to moderate changes in current magnitude and phase. So at a single frequency, the spacing won't matter much as long as you can get about the right current magnitude and phase. But take a look at how the values in the I MAG and REL PHA columns change with frequency. With closer spacing, you might find that they change more than they do with wider spacing. This means that your f/b ratio will deteriorate more as you go away from the design frequency.

The EZNEC demo program is useful for looking at the pattern and seeing just how much it'll change with frequency. A FDSP model is one of the example files. To see the pattern at any frequency, simply modify the second current source of that model to reflect the values from the FDSP program. For example, if the FDSP program shows I MAG = 0.9296 and I PHA = 142.1 at 14.20 MHz, change the EZNEC Source 2 Amplitude to 0.9296, the Source 2 Phase to 142.1, and the frequency to 14.2 MHz to see the pattern at that frequency. This way you can see what the pattern will be at each frequency for a particular design. You can get the EZNEC demo from http://eznec.com. It's free.

I'd used Acid Flux (The liquid kind you buy in a bottle for Plumbers)
initially. Soak it in the stuff for a minute or so, then use a torch to burn it
off. Do that a couple times then rinse it off. Then Solder it with your
standard Rosin flux based 60/40 solder and a big Weller pistol grip solder gun.
Never a problem.. works every time for me.

I built my own windom type antenna..full size dipole length on 80 meters..fed with (heavy duty 400 ohm window type feeder approx 65 ft) all the way into the shack to my johnsons matchbox. I get good reports on all bands (generally). It seems to exhibit some directivity on 10 meters off the long end..on 20 seems to load and work very well..Id say its a good general purpose wire antenna and if you could only put one wire up..id recommend it..Earl VE3AB

I am surprised that no-one has mentioned the Geoclock program. An option of it is to have an azimuthal map, centered on ones own location, with the ability to enter a prefix and get bearings (to and from) and the local time there. An added bonus is the sunrise and sunset times. it shows the daylight and dark patterns, in real time, along with the Sun and Moon overhead positions.

I keep the program minimized, and can call it up fast, to get both the ID of a call prefix (I cannot remember them all) and the bearing. The display is the map, and the bearing is shown.Many different maps are included, at different scales, in additon to the world azimuth map.

I just upgraded mine, from a version I have run for several years.

Thanks for the helpful info Roy. I'll be cutting & raising the FDSP today.
I'm trying to improve my signal on the 20 meter phone band from a temporary
location. I'm using a dipole now which i'll leave up for comparison.

Thanks again.

2943. varnish on wire antenna affect RF capabilities??

Newsgroup: rec.radio.amateur.antenna

I am going to erect a wire HF antenna...for 10-80 meters. This will be in a very smoggy, hostile environment. I know from experience that bare wire at this location gets corroded and brittle within a short time.

I am going to use 16 gauge stranded Copperweld wire. Not insulated. I have _ A LOT_ of it on hand, already paid for.

I am thinking of coating this stranded wire with a good UV resistant varnish that I also have on hand, that I have experience with.

Lets assume that the varnish penetrates well, and that each individual strand is 90% coated with varnish, on average.

Will this thin coating of varnish have a negative on my transmit and receive capabilities, at the 100 watt level? If yes, could you please quantify the effect, in a general manner?

2945. Antenna tuner observations.....

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-10 15:39:56 UTC
From: Bill Russell <willy@global2000.net>
Message-ID: <it2d6u8joehcstp8qccvdqtfj6cqia0ats@4ax.com>
Source record: 148932

Hi all,
Just a few thoughts on my search for the "perfect antenna tuner". As some of u might remember from my last posts, I was looking for the best antenna tuner I could use on my 130ft. dipole fed with 450 ohm window line. Well after much searching, reading opinions some of which were posted on this new group and buying a $1000 tuner made by a reputable manufacture, I discovered the following:

The $1000 tuner went back the next day. This tuner was very well made used excellent parts including a big current balun at the input of the tuner. I did an AB test between this tuner and a Johnson 250watt matchbox and the Johnson blew it away for tuning balanced lines. I did the same tests with a borrowed MFJ with the same results. The Johnson was also borrowed and I needed to buy my own but I needed a bigger unit to handle full power and that was the reason for my search. I finally bought a kilowatt Johnson matchbox on ebay (epay) and am very happy. The $1000 tuner would only tune 160 and 80 meters using the above antenna with 67 feet of feedline. Both Johnsons tuned the antenna fine. The $1000 unit had a lot of insertion loss on the receive signal. The Johnson was 2 to 5 s units stronger on receive. I dont know the losses on transmitt because I could not measure it. The theory involved explaining the differences between the different tuners is a lot over my head but the things I read about link coupled tuners compared to "single ended tuners using a balun" was right on the money. If you want to tune a balanced antenna fed with balanced line.....use a link coupled tuner with the same design as the old Johnsons. I know there is more to the design than just the link coupling such as the differential voltage divider Johnson used but as i said, this is a little over my head.
Anyway I just though some of u might want to know what I discovered.

BTW.....this is NOT a review of the $1000 tuner as I am sure it works fine tuning coax.

2946. AR-22 with XL-1 Problem/questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-10 16:25:03 UTC
From: Rick Ruhl <ricker@cssincorp.com>
Message-ID: <r5x98.122095$h31.8662069@e420r-atl1.usenetserver.com>
Source record: 148934

I picked up an AR-22 rotor with an XL-1 controller at a hamfest yesterday. Went to test it and found a minor issue with it. I'm sure with all the experiences hams in this group, you can help me find an answer. BTW, which AR-22 is this. Ive seen that there are manuals for two different types.

On the bottom of the rotor, it has

AR22 SER4 Z7

and on the control box;

XL-1 November 1980.

Hooked up the rotor and calibrated the XL-1. It will turn 360 degrees, then back, then on the 3rd 360 turn, the rotor and control box will stop at a random point. Turning the rotor control either way doesn't make the power come back on or the rotor turn.

However, if I unplug the control box and leave it sitting for a little while, come back in and turn it on, then it'll work fine for 1 or 2 360 degree turns. Looking on Deja archive (yes, I know it's google archives now <grin>), there's a mention of capacitor issue similar to this.

1. Does this sound like a capacitor problem

2. If so, where is this capacitor located?(in the rotor or in the control box) and what's the best place to get a replacement.

3. If not, where should I start looking for the issue?

Thanks

Rick - W4PC

IF its a dipole for the frequency you want to use, the impedance will
generally be darn close to 72 ohms which is a good enough match for
standard 50/75 ohm coax.
GL,
Bill

2951. VHF LPA design question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-10 17:04:15 UTC
From: post_to_usenet@hotmail.com
Message-ID: <b6b4e772.0202100904.279ed030@posting.google.com>
Source record: 148939
Body handling: Inline uuencoded payload not displayed: LPA_VHF.ZIP

Hi,

I would like to know if it is possible to use 2 coax cables
as the transmission line between elements in a LPA, so as
to get a 100 ohm .65 VF line between elements. Like in:

```
|
| |
| | |
| | | |
| ____ ___ | __ ___ |___ __ |
+)___ \ / __)+)_ \ / __)+)_ \ / _)+\
____\/ /___ ___\/ /__ ___\/ /_ \ _
+)____/\____)+)___/\___)+)___/\__)+--)_ \
| | | | \ \
| 2x50ohm | | | | |
| between | | | | 75 ohm coax
| elements | | | feedline with
| | | some kind of
~ ~ balun
```

If the answer is yes, would you then join the braids between
the two coax? (I suppose yes), and more important: would you
join the braids between coax coming from the previous element
and those going to the next elemnt?

This would be for the attached antenna model. SWR OK @ 75 ohm
in 115~285 MHz, but above 220 MHz the vertical pattern seems
to become a "cloud warmer".

Do you think it could be built?

Toni

A dead giveaway is the guy who is a well-known gear seller who hasn't
plugged it in to try it out.
But, in fairness, alot of this stuff DOES show up at yard sales, CB
jamborees, estate auctions, and speaking with some knowledge-divorcees
will sell good gear for pennies on the dollar just as revenge :-)....and
dumpster diving. I'm sure we've all heard the story about the SX-88
found sitting beside a dumpster.

50/75 ohm coax to a dipole doesn't need any stub or balun. Worst case
reading with a 50-ohm rig/meter would be about 1.4:1
You mention that its an 'army' dipole for 144 Mhz...I don't know what
that might be but you can simply measure the length of it to determine
if its in fact made for 144 MHz.
Trying it is highly recommended if the length is somewhat accurate.

It's an R&S dipole.The frequency range is from 120 to 160 MHz.And since when don't you need a stub to run a dipole directly on a coaxcable ?? A symmetric antenna to an unsymmetric cable ??

Tom,
There will be no difference in impedance if you do not
use a balun or stub with the dipole. There will be a
difference in the radiation pattern, though.

Tom, DL7JSK wrote:
"And since when don`t you need a stub to run a dipole directly on coax cable?"

If you are using the dipole at its resonant frequency it may be a good impedance match to the cable, Then, if you`ve made the outside of the cable an unattractive path for the signal, you don`t need a stub.

For accommodating an unbalanced transmission line at a balanced antenna, an extra 1/2-wave of coax may be inserted in the feed to one of the elements of the dipole to make a coax balun. This multiplies the line feed impedance seen by the antenna by a factor of four. A 1/4-wave "bazzooka" is another fix.

A quarter-wave stub can shunt an antenna feed with no ill effect. It may even improve the bandwidth. If the quarter-wave stub were adjustable like a slide-trombone it could be used to tune out antenna reactance.

Tom`s R&S dipole may have a stub for tuning or balancing. We don`t know enough.

Best regards, Richard Harrison, KB5WZI

2963. Re: How do they get the stuff?

There's a TS-440 in there now listed as being found in the trunk of a car
just before the car went into the crusher.

To begin with, the dimensions of your elements are more along the
lines for 137-141 MHz. I find the best performance with the longest
element at 0.51 wl at the lowest frequency and the shortest element at
0.35 wl at the highest frequency needed.
